THE KERNEL OF RIBET’S ISOGENY FOR GENUS THREE SHIMURA CURVES

JOSEP GONZÁLEZ, SANTIAGO MOLINA

Abstract. There are exactly nine reduced discriminants $D$ of indefinite quaternion algebras over $\mathbb{Q}$ for which the Shimura curve $X_D$ attached to $D$ has genus 3. We present equations for these nine curves and, moreover, for each $D$ we determine a subgroup $c(D)$ of cuspidal divisors of degree zero of $\text{Jac}(X_0(D))^\text{new}$ such that the abelian variety $\text{Jac}(X_0(D))^\text{new}/c(D)$ is the jacobian of the curve $X_D$.

1. Introduction

Let $D$ be the reduced discriminant of an indefinite quaternion algebra over $\mathbb{Q}$. Let us denote by $X_D/\mathbb{Q}$ the Shimura curve attached to $D$. In [16], K. Ribet established the existence of an isogeny defined over $\mathbb{Q}$ between $\text{Jac}(X_0(D))^\text{new}$ and $\text{Jac}(X_D)$ by proving that both abelian varieties have the same $L$-series, but it is not known an explicit description of such an isogeny. A. P. Ogg studied the problem of determining the kernel of an isogeny of minimal degree and conjectured that it may be a subgroup of the group of cuspidal divisors of degree zero of the curve $X_0(D)$. Moreover, for some particular cases that $D$ is the product of two primes, he predicted which subgroup should be this kernel (cf. [15]).

When the genus $g$ of $X_D$ is 1, there are exactly five discriminants $D = 14, 15, 21, 33$ and 34. In all these cases, two elliptic curves defined over $\mathbb{Q}$ of conductor $D$ are isomorphic over $\mathbb{Q}$ if and only if both have the same type of reduction at every prime dividing $D$. Therefore, the elliptic curve $\text{Jac}(X_D)$ can be determined among the isomorphism classes of elliptic curves over $\mathbb{Q}$ of conductor $D$ in Cremona’s tables by using the theory of Cerednik-Drinfeld. For the subgroup $c(D)$ of cuspidal divisors of degree zero displayed in the next table

\[
\begin{array}{|c|c|c|c|c|}
\hline
D & 14 & 15 & 21 & 33 & 34 \\
\hline
|c(D)| & (3(0) - 3(\infty)) & \{0\} & (2(0) - 2(\infty)) & \{0\} & (0) - (\infty) \\
\hline
\end{array}
\]

one has that $\text{Jac}(X_0(D))^\text{new}/c(D) \simeq \text{Jac}(X_D)$. This result can be obtained by checking that $\text{Jac}(X_0(D))^\text{new}/c(D)$ and $\text{Jac}(X_D)$ have the same type of reduction at every prime dividing $D$ or checking that the lattice of $\text{Jac}(X_0(D))^\text{new}/c(D)$ corresponds to the elliptic curve $\text{Jac}(X_D)$.

Key words and phrases. Shimura curves, genus three hyperelliptic curves.
For $g = 2$, there are exactly three curves $X_D$ and a kernel $c(D)$ for these three cases is presented in Theorem 3.1 of [5]:

<table>

In this case, once an equation for $X_D$ is determined, the proof is based on the fact that $X_D$ is bielliptic and the lattices of $\text{Jac}(X_0(D))^{\text{new}}$ and $\text{Jac}(X_D)$ can be handled through their elliptic quotients.

The aim of this paper is double. On the one hand, to determine equations for all curves $X_D$ of genus three; although these nine curves have a hyperelliptic involution defined over $\mathbb{Q}$, uniquely seven of them are hyperelliptic over $\mathbb{Q}$. On the other hand, to check the existence of a subgroup of $\text{Jac}(X_0(D))^{\text{new}}(\mathbb{Q})$ formed by cuspidal divisors of $X_0(D)$ to be the kernel of an isogeny between $\text{Jac}(X_0(D))^{\text{new}}$ and $\text{Jac}(X_D)$ for each of these values of $D$.

In [12], it is given a method to compute equations for Atkin-Lehner quotients of Shimura curves attached to an odd discriminant $D$ which are hyperelliptic over $\mathbb{Q}$ and some equations are computed. This method has a computational limitation since it exploits the MAGMA instruction $\text{IndexFormEquation}$ that only applies for general number fields of degree at most four. For this reason, in section 3, we show how to obtain equations for all Shimura curves of genus three from certain particular equations of their Atkin-Lehner quotients, where the number fields involved are of degree smaller than five. In section 4, first we determine equations of the Atkin-Lehner quotients when $D$ is even, which is more laborious than the odd case; next, in Theorem 4.5 we present a list of all genus three equations, together with the projections onto their Atkin-Lehner quotients in Proposition 4.4. Finally, in Theorem 5.1 of section 5, for each of the the nine curves of genus 3 we present a subgroup of cuspidal divisors of degree zero of $X_0(D)$ which provides in $\text{Jac}(X_0(D))^{\text{new}}(\mathbb{Q})$ the kernel of a Ribet’s isogeny.

2. Genus three Shimura curves and their Atkin-Lehner quotients

Let $X_D / \mathbb{Q}$ be the Shimura curve and, for a divisor $m | D$, let us denote by $\omega_m$ the corresponding Atkin-Lehner involution of $X_D$.

**Proposition 2.1.** The curve $X_D$ has genus 3 exactly for the following values of $D$:

$$2 \cdot 31, 2 \cdot 41, 2 \cdot 47, 3 \cdot 13, 3 \cdot 17, 3 \cdot 19, 3 \cdot 23, 5 \cdot 7, 5 \cdot 11.$$ 

In all these cases, $X_D$ is hyperelliptic over $\overline{\mathbb{Q}}$ and the hyperelliptic involution $w$ is the Atkin-Lehner involution $\omega_D$ except for the values $D = 57$ and 82, for which $w$ is $\omega_{19}$ and $\omega_{41}$ respectively. Moreover, $X_D$ is hyperelliptic over $\mathbb{Q}$ if and only if $w = \omega_D$.

**Proof.** The first part follows from the genus formula for $X_D$ and the remaining of the statement can be found in Theorem 7 of [14].

From now on, $D$ is one of these nine values of the above proposition. By [8], we know that the group of the automorphisms of the Shimura curve $X_D$ is the group of the Atkin-Lehner involutions $\{\omega_m : m | D\}$ and, thus, we have that $\text{Aut}(X_D) = \text{Aut}_\mathbb{Q}(X_D) \simeq (\mathbb{Z} / 2\mathbb{Z})^2$. We denote by $w$ the hyperelliptic involution of $X_D$ and by $u$ the unique Atkin-Lehner involution such that the quotient curve $X^u := X_D / \langle u \rangle$
has genus one. It follows that \( \text{Aut}(X_D) = \{1, u, w, v\} \), where \( v = u \cdot w \), and the quotient curves \( X^{(w)} := X_D/\langle w \rangle \) and \( X^{(v)} := X_D/\langle v \rangle \) have genus 0 and 2 respectively. The Atkin-Lehner involutions \( \omega_m = u, \omega_m = v \) and \( \omega_m = w \) are displayed in the following table:

<table>
<thead>
<tr>
<th>( D )</th>
<th>( 2 \cdot 31 )</th>
<th>( 2 \cdot 41 )</th>
<th>( 2 \cdot 47 )</th>
<th>( 3 \cdot 13 )</th>
<th>( 3 \cdot 17 )</th>
<th>( 3 \cdot 19 )</th>
<th>( 3 \cdot 23 )</th>
<th>( 5 \cdot 7 )</th>
<th>( 5 \cdot 11 )</th>

Given a nontrivial involution \( \iota \in \text{Aut}(X_D) \), let us denote by \( \pi : X_D \to X^{(\iota)} \) the natural projection and \( \mathcal{F}_\iota \) denotes the set of fixed points under \( \iota \). Hence, \( \mathcal{F}_v = \emptyset \), \( |\mathcal{F}_w| = 4 \) and \( |\mathcal{F}_w| = 8 \). For \( \iota \neq v \), the number field generated by the coordinates of the projection \( \pi_u(P) \) of a point \( P \in \mathcal{F}_\iota \) can be found in [6]. For instance, if \( U \in \mathcal{F}_u \) we have

\[
\begin{array}{c|c|c}
D & \mathbb{Q}(U) & \mathbb{Q}(\pi_u(U)) = \mathbb{Q}(\pi_w(U)) \\
\hline
2 \cdot 31 & \mathbb{Q}((\sqrt{-1}) \text{ or } \mathbb{Q}((\sqrt{-2})) & \mathbb{Q} \\
2 \cdot 41 & \mathbb{Q}(\sqrt{-3} + 4\sqrt{-2}) & \mathbb{Q}(\sqrt{-2}) \\
2 \cdot 47 & \mathbb{Q}(\sqrt{-1}) \text{ or } \mathbb{Q}(\sqrt{-2}) & \mathbb{Q} \\
3 \cdot 13 & \mathbb{Q}(\sqrt{-13}, \sqrt{13}) & \mathbb{Q}(\sqrt{-1}) \\
3 \cdot 17 & \mathbb{Q}(\sqrt{-3}) & \mathbb{Q} \\
3 \cdot 19 & \mathbb{Q}(\sqrt{3}, \sqrt{-3}) & \mathbb{Q}(\sqrt{-3}) \\
3 \cdot 23 & \mathbb{Q}(\sqrt{-3}) & \mathbb{Q} \\
5 \cdot 7 & \mathbb{Q}(\sqrt{-7}) & \mathbb{Q} \\
5 \cdot 11 & \mathbb{Q}(\sqrt{-5}, \sqrt{5}) & \mathbb{Q}(\sqrt{-1}) \\
\end{array}
\]

where for \( D = 62, 94 \), i.e. \( u = \omega_2 \), there are two fixed points generating \( \mathbb{Q}(\sqrt{-1}) \) while the other two fixed points generate \( \mathbb{Q}(\sqrt{-2}) \).

The involution \( w \) induces involutions on the curves \( X^{(v)} \) and \( X^{(u)} \) that will be also denoted by \( w \). For the genus two curve \( X^{(v)} \), \( w \) is the hyperelliptic involution and, thus, the curve \( X^{(v)} \) admits a hyperelliptic model over \( \mathbb{Q} \).

For the curve \( X^{(u)} \), since \( w \) is defined over \( \mathbb{Q} \), it has an equation of the form \( y^2 = F(x) \) with \( F(x) \in \mathbb{Q}[x] \) of degree 3 or 4 and for which the involution \( w \) acts sending \((x, y)\) to \((x, -y)\). Any equation for \( X^{(u)} \) of the form \( y^2 = G(x) \) with \( G(x) \in \mathbb{Q}[x] \) of degree 3 or 4 for which the action of \( w \) is given by \((x, y) \mapsto (x, -y)\) is equivalent over \( \mathbb{Q} \) to \( y^2 = F(x) \), i.e. there exist

\[
\begin{pmatrix}
\alpha & \beta \\
\gamma & \delta
\end{pmatrix} \in \text{GL}(2, \mathbb{Q}) \quad \text{and} \quad \lambda \in \mathbb{Q}^*
\]

such that

\[
G(x) = \lambda^2 F(\frac{\alpha x + \beta}{\gamma x + \delta})(\gamma x + \delta)^4.
\]

3. **Equations for** \( X_D \) **from its Atkin-Lehner quotients**

In [12], S. Molina gives a method to compute equations for Atkin-Lehner quotients of Shimura curves attached to an odd discriminant \( D \) which are hyperelliptic over \( \mathbb{Q} \). In particular, for the case that \( X_D \) has genus 3, in Table 2 of [12] it is
showed equations for $X_D$ when $D = 39, 55$ and for $X^{(v)}$ when $D = 35, 51, 57, 69$. In this section we show how we can obtain an equation for $X_D$, even if $X_D$ is not hyperelliptic over $\mathbb{Q}$, from certain particular equations for $X^{(u)}$ and $X^{(v)}$.

We recall that for a hyperelliptic curve $Y$ of any genus $g > 1$ defined over a field $K$ of characteristic $\neq 2$ and a point $P \in Y(\overline{K})$, there exists a basis $\{\lambda_i\}_{1 \leq i \leq g}$ of $H^0(Y, \Omega^1)$ such that for all $i$:

$$\text{ord}_{P} \lambda_i = \begin{cases} 2i - 2 & \text{if } P \text{ is a Weierstrass point}, \\ i - 1 & \text{otherwise}. \end{cases}$$

For such a basis, the functions $x = \nu_1^n/\nu_2$, $y = \nu_3/\nu_2$ generate the function field of $Y$ and provide a hyperelliptic model for $Y$, that is $y^2 = F(x)$ for some polynomial $F(x) \in \overline{K}[x]$ without double roots, of degree $2g + 1$ or $2g$ according to $P$ is a Weierstrass point or not. If the hyperelliptic involution $w$ is defined over $K$ and $P$ provides a $K$-rational point of $Y/\langle w \rangle$, then we can take $\lambda_i \in H^0(Y, \Omega_Y^1)$ for all $i$ and, thus, $f(x) \in K[x]$ (for instance, see Lemma 2.5 of [1]).

In our particular setting, we point out the following facts:

(a) The curve $X_D$ has a hyperelliptic model over $\mathbb{Q}$ if and only if $X^{(w)}(\mathbb{Q}) \simeq \mathbb{P}^1(\mathbb{Q})$, i.e. $D \neq 57, 82$. Since $X_D(\mathbb{R}) = \emptyset$, a point $Q \in \pi_w^{-1}(X^{(w)}(\mathbb{Q}))$ if and only if there is an integer $e < 0$ such that $Q \in X_D(\mathbb{Q}(\sqrt{e}))$ with $w(Q) = Q^e$, where $\sigma$ is the nontrivial automorphism in $\text{Gal}(\mathbb{Q}(\sqrt{e})/\mathbb{Q})$. In this case, $X_D$ admits an affine equation of the form:

$$\begin{align*}
y^2 &= e F(x), \\
F(x) &\in \mathbb{Q}[x],
\end{align*}$$

where $F$ is monic without double roots, $x \in \mathbb{Q}(X_D)$ and $\text{div } x + (Q) + (w(Q)) \geq 0$. The curve $X_D$ does not have any real point (cf. [18]) and, thus, does not have any rational Weierstrass point. Therefore, $\deg F = 8$.

(b) From the equality

$$H^0(X_D, \Omega^1_{X_D/\mathbb{Q}}) = \pi_u^* \left( H^0(X^{(u)}, \Omega^1_{X^{(u)}/\mathbb{Q}}) \right) \oplus \pi_v^* \left( H^0(X^{(v)}, \Omega^1_{X^{(v)}/\mathbb{Q}}) \right),$$

we can take a basis $\{\nu_1, \nu_2, \nu_3\}$ of $H^0(X_D, \Omega^1_{X_D/\mathbb{Q}})$ such that $\nu_1$ lies in $\pi_u^*(H^0(X^{(u)}, \Omega^1_{X^{(u)}/\mathbb{Q}}))$ and $\nu_2, \nu_3$ are in $\pi_v^*(H^0(X^{(v)}, \Omega^1_{X^{(v)}/\mathbb{Q}}))$. Since the hyperelliptic involution $w$ acts on $H^0(X_D, \Omega^1_{X_D/\mathbb{Q}})$ as the multiplication by $-1$ and $w = u \cdot v$, the action of $u, v$ on this basis is the following:

$$\begin{array}{ccc}
\nu_1 & \nu_2 & \nu_3 \\
\hline
u & \nu_1 & -\nu_2 & -\nu_3 \\
v & -\nu_1 & \nu_2 & \nu_3
\end{array}$$

It is clear that $\text{div } \nu_1 = \sum_{U \in \mathcal{F}_u} (U)$.

(c) The set of Weierstrass points of $X^{(v)}_D$ is formed by the four points of the set $\pi_v(\mathcal{F}_w)$ and the two points of $\pi_v(\mathcal{F}_u)$.

Now, we split the nine cases in three types and we present for each of them a particular class of equations. The two first types correspond to the case that $X_D$ is hyperelliptic over $\mathbb{Q}$.

3.1. **Type 1:** $D \in \{35, 51, 62, 69, 94\}$. 
Assume $D \in \{35, 51, 62, 69, 94\}$. Then, the curve $X^{(v)}$ admits an equation of the form

$$y^2 = e \left(X^4 + aX^3 + bX^2 + cX + d\right)$$

for some $a, b, c, d, e \in \mathbb{Q}$, where $\pi_\nu(F_u)$ is the set of Weierstrass points corresponding to $X = 0, \infty$ and $\mathbb{Q}(\sqrt{c})$ is the field of definition of a point $U \in F_u$. For any such an equation,

(i) if $D \in \{35, 51, 69\}$, then

$$y^2 = e(x^8 + ax^6 + bx^4 + cx^2 + d)$$

is an equation for $X_D$ and $y^2 = e(\left(4 + aX^3 + bX^2 + cX + d\right)$ is an equation for $X^{(u)}$ for which $w(X, y) = (X, -y)$.

(ii) if $D \in \{62, 94\}$ and, moreover, $y^2 = e(\left(4 + aX^3 + bX^2 + cX + d\right)$ is an equation for $X^{(u)}$ with $w(X, y) = (X, -y)$, then

$$y^2 = e(x^8 + ax^6 + bx^4 + cx^2 + d)$$

is an equation for $X_D$.

**Proof.** Every $Q \in F_u$ is defined over an imaginary quadratic field (cf. Table 1) and $w(Q)$ is the Galois conjugate of $Q$. We take $Q \in F_u$. Since the Weierstrass point $\pi_u(Q)$ of $X^{(v)}$ is rational, we can choose $\nu_2 \in \pi^{-1}_v \left(H^0(X^{(v)}, \Omega^1_{X^{(v)}, Q})\right)$ such that

$$\text{div } \nu_2 = 2(Q) + 2(w(Q)).$$

Set $x = \nu_1/\nu_2$ and $y = dx/\nu_2$. By scaling $y$ by a suitable rational if necessary, $x$ and $y$ satisfies a relationship as in (1), where $\mathbb{Q}(\sqrt{c})$ is the field of definition of $Q$. The involutions $u$ and $v$ act by sending $(x, y)$ to $(-x, y)$ and $(-x, -y)$ respectively. Therefore, there is a polynomial $G(x) = x^4 + aX^3 + bX^2 + cx + d \in \mathbb{Q}[x]$ such that

$$X_D : \quad y^2 = eG(x^2),$$

$$X^{(u)} : \quad y^2 = eG(X),$$

$$X^{(v)} : \quad Y^2 = eXG(X),$$

where $X = x^2$ and $Y = yx$.

It is clear that $w$ acts on $X^{(u)}$ by sending $(X, y)$ to $(X, -y)$. Since $\text{div } x = (Q') + (w(Q')) - (Q^2) - (w(Q))$ for $Q' \in F_u \setminus \{Q, w(Q)\}$, the set of points on $X_D$ corresponding to $x = 0, \infty$ is $F_u$ and, thus, $X = 0$ and $X = \infty$ yield the set $\pi_v(F_u)$ on the curve $X^{(v)}$. Since $\mathbb{Q}(\sqrt{e})$ is the field of definition of $Q'$, for $D \neq 62, 94$ one has $d \in \mathbb{Q}^2$ and otherwise $2d \in \mathbb{Q}^2$.

Let $T^2 = eZF(Z)$ be any equation of $X^{(v)}$ with $F(Z) \in \mathbb{Q}[Z]$ monic of degree 4 and such that $\pi_\nu(F_u)$ is the set of points on $X^{(v)}$ corresponding to $Z = 0, \infty$. Since the group $\text{Aut}(X^{(v)})$ is commutative (cf. Proposition 1.5 of [8]), the set of fixed points of $u$ on $X^{(v)}$ is stable under the action of all automorphisms of the curve. Hence, any isomorphism between $T^2 = eZF(Z)$ and $Y^2 = eXG(X)$ must send the points $Z = 0$ and $Z = \infty$ to the points $X = 0$ and $X = \infty$. Therefore, it must be of the form $(X, Y) = (\alpha Z, \lambda T)$ or $(X, Y) = (\alpha/\lambda, \lambda T/Z^3)$ for some $\alpha, \lambda \in \mathbb{Q}^*$. Observe that if $d \in \mathbb{Q}^2$, changing $(x, y)$ by $(1/x, \sqrt{a}y/x^4)$ in the equation $y^2 = eG(x^2)$ if necessary, we can assume that the isomorphism sends $Z = 0$ to $X = 0$ and, thus, $(X, Y) = (\alpha Z, \lambda T)$.

If $(X, Y) = (\alpha Z, \lambda T)$, it is easy to check that $\alpha^5 = \lambda^2$ and, thus, $(\alpha, \lambda) = (\beta^2, \beta^5)$ for some $\beta \in \mathbb{Q}^*$. The changes $(x, y) = (\beta z, \beta^4 t)$ and $(X, y) = (\beta^2 Z, \beta^4 t)$ provide
isomorphisms between the genus three curves $y^2 = eG(x^2)$ and $t^2 = eF(z^2)$ and the genus one curves $y^2 = eG(X)$ and $t^2 = eF(Z)$ respectively.

If $(X, Y) = (\alpha/Z, \lambda T/Z^3)$, then $d\alpha = \lambda^2$. If, moreover, the equation

$$t^2 = \frac{e}{d}G\left(\frac{\alpha}{Z}\right)Z^4$$

is equivalent to the equation $y^2 = eG(X)$, then $d$ must be a rational square and, thus, the statement is proved. \qed

**Remark 3.1.** According to Table 1, the values $e$ of the above proposition, up to rational square factors, are:

<table>
<thead>
<tr>
<th>$D$</th>
<th>3 · 17</th>
<th>3 · 23</th>
<th>5 · 7</th>
</tr>
</thead>
<tbody>
<tr>
<td>$e$</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

and for $D = 62, 94$ we will choose $e = -1$.

### 3.2. Type 2: $D \in \{39, 55\}$

**Proposition 3.2.** Assume $D \in \{39, 55\}$. Let $e < 0$ be an integer for which there is a point $Q$ defined over $\mathbb{Q}(\sqrt{e})$ such that $\pi_w(Q) \in X^{(w)}(\mathbb{Q})$. Then, $X^{(v)}$ admits an equation of the form

$$Y^2 = e\left(X^4 + aX^3 + bX^2 + cX + d\right)(X^2 + 4)$$

for some $a, b, c, d \in \mathbb{Q}$, where $\pi_w(F_u)$ is the set of Weierstrass points corresponding to the roots of $X^2 + 4$ and

$$V^2 = e\left(X^4 + aX^3 + bX^2 + cX + d\right)$$

is an equation for $X^{(u)}$ with $w(X, V) = (X, -V)$. For any such an equation for $X^{(v)}$, the curve $X_D$ has the equation

$$y^2 = e(x^8 + ax^7 + b x^6 + C x^5 + E x^4 - C x^3 + B x^2 - a x + 1),$$

where $B = b - 4$, $C = c - 3a$, $E = d - 2b + 6$.

**Proof.** In this case, $Q \notin F_u$ for any choice of $Q$ in $\pi_w^{-1}(X^{(w)}(\mathbb{Q}))$. Since $u$ is defined over $\mathbb{Q}$, also $u(Q) \in X_D(\mathbb{Q}(\sqrt{e}))$ and $v(Q) = u(w(Q)) = u(Q)^{\sigma}$.

We can take $\lambda_1, \lambda_2 \in H^0(X_D, \Omega_{X_D/\mathbb{Q}}^1)$ such that:

$$\text{div } \lambda_1 = (Q) + (w(Q)) + (v(Q)) + (u(Q)),$$

$$\text{div } \lambda_2 = 2(Q) + 2(w(Q)).$$

Set $x = \lambda_1/\lambda_2$ and $y = dx/\lambda_2 = x dx/\lambda_1$. Then, we have a relationship as in (1) by scaling $y$ by a suitable rational if necessary. Due to the fact that

$$\text{div } u^*(x) = \text{div } u^*(\lambda_1) - \text{div } u^*(\lambda_2) = \text{div } \lambda_2 - \text{div } \lambda_1 = - \text{div } x,$$

it is clear that $u^*(x) = \varepsilon/x$ for some $\varepsilon \in \mathbb{Q}^*$. The divisor of $\lambda_1$ is invariant under $u$ and $\lambda_1 \notin \langle \nu_1 \rangle$ since $\text{div } \nu_1 = \sum_{U \in F_u}(U)$. Therefore, it must be $u^*(\lambda_1) = -\lambda_1$. Hence, $u^*(y) = y \varepsilon^2/x^4$ and $u$ sends $(x, y)$ to $(\varepsilon/x, \varepsilon^2/x^4)$. Note that $\varepsilon \notin \mathbb{Q}^2$, otherwise $\pi_w(F_u) \subset X^{(w)}(\mathbb{Q})$. By scaling $x$ by a suitable rational, we can assume that $\varepsilon$ is square-free. Since $\mathbb{Q}(\sqrt{\varepsilon}) \subseteq \mathbb{Q}(\pi_u(U))$ for all $U \in F_u$, it follows that $\varepsilon = -1$ (see Table 1). So,

(2)

$$X_D : y^2 = (x^8 + Ax^7 + Bx^6 + Cx^5 + Ex^4 - Cx^3 + Bx^2 - Ax + 1),$$

$$X^{(u)} : V^2 = e\left(X^4 + AX^3 + (B + 4)X^2 + (C + 3A)X + E + 2B + 2\right)(X^2 + 4),$$

$$X^{(v)} : Y^2 = e\left(X^4 + AX^3 + (B + 4)X^2 + (C + 3A)X + E + 2B + 2\right)(X^2 + 4),$$

with
for some $A, B, C, E \in \mathbb{Q}$ and where

$$X = x - 1/x, \quad V = y/x^2 \quad \text{and} \quad Y = V (x + 1/x) = y (x^2 + 1)/x^3.$$ 

Writing $a = A$, $b = B + 4$, $c = C + 3A$ and $d = E + 2B + 2$, we recover the notation as in the statement. Since the points of $\mathcal{F}_u$ correspond to the points whose $x$-coordinates satisfy $x^2 = -1$, it follows that their projections into $X^{(v)}$ satisfy $X^2 = -4$. Moreover, $w$ acts on $X^{(u)}$ by sending $(X, V)$ to $(X, -V)$.

Set $g(x) := e(x^8 + A x^7 + B x^6 + C x^5 + E x^4 - C x^3 + B x^2 - A x + 1)$ and $G(X) := X^4 + a X^3 + b X^2 + c X + d$. Let $T^2 = e (Z^2 + 4) F(Z)$ be any equation of $X^{(v)}$ with $F(Z) \in \mathbb{Q}[Z]$ monic of degree 4 and such that $\pi_v(\mathcal{F}_u)$ is the set of points corresponding to $Z^2 = -4$ and $S^2 = e F(Z)$ is an equation of $X^{(u)}$ equivalent to $V^2 = e G(X)$. Changing $(x, y)$ by $(-x, y)$ in the equation given in (2) for $X_D$ if necessary, we can assume that an isomorphism defined over $\mathbb{Q}$ between $T^2 = e (Z^2 + 4) F(Z)$ and $Y^2 = e (X^2 + 4) G(X)$ sends $Z = 2i$ and $Z = -2i$ to $X = 2i$ and $X = -2i$ respectively. Therefore, this isomorphism must be of the form

$$(X, Y) = \left( -\frac{4}{Z}, \lambda \frac{T}{Z^3} \right) \quad \text{or} \quad (X, Y) = \left( \frac{Z - 4\gamma}{\gamma Z + 1}, \lambda \frac{T}{(\gamma Z + 1)^3} \right)$$

for some $\gamma, \lambda \in \mathbb{Q}$.

If $(X, Y) = (-4/Z, \lambda T/Z^3)$, we consider the equation $t^2 = f(z)$ obtained from the equation $y^2 = g(x)$ by means of the change

$$(x, y) = ((z - 1)/(z + 1), \lambda 2 t/(z + 1)^4).$$

It is easy to prove that

$$(3) \quad \left( \frac{t}{z^4} \right)^2 = f \left( -\frac{1}{z} \right), \quad Z = z - \frac{1}{z}, \quad S = \frac{t}{z}, \quad T = \frac{t^2 + 1}{z^3}.$$ 

Hence, $t^2 = f(z)$ is the equation of the genus three curve obtained from the equation $T^2 = e (Z^2 + 4) F(Z)$ after applying the rule given in the statement.

For the isomorphism $(X, Y) = ((Z - 4\gamma)/(\gamma Z + 1), \lambda T/(\gamma Z + 1)^3)$, we get that $\gamma (1 + 4 \gamma^2)(a + \gamma + b \gamma + c \gamma^2 + d \gamma^3) = \lambda^2$. Moreover, since

$$S^2 = e F(Z) = \frac{e}{\gamma (a + \gamma + b \gamma + c \gamma^2 + d \gamma^3)} G \left( \frac{Z - 4\gamma}{\gamma Z + 1} \right) (\gamma Z + 1)^4,$$

is equivalent to $V^2 = e G(X)$, $\gamma (a + \gamma + b \gamma + c \gamma^2 + d \gamma^3)$ must be a rational square and, thus, also $1 + 4 \gamma^2 \in \mathbb{Q}^2$. Let $\nu$ be any root of the polynomial $\gamma x^2 + x - \gamma$, which is a rational number different from $\pm 1$. The change

$$(x, y) = \left( \frac{z - \nu}{\nu z + 1}, -\lambda \frac{\nu^2 + 1}{(\nu^2 - 1)^3} \frac{t}{\nu z + 1} \right)$$

provides an equation $t^2 = f(z)$ for $X_D$ satisfying all conditions in (3). Hence, the statement is proved.

**Remark 3.2.** By the theory of Heegner points, in the previous proposition we can choose $e$, up to rational square factors, to be $-7$ for $D = 39$ and $-3$ for $D = 55$. 

3.3. Type 3: $D = 57, 82$.

**Proposition 3.3.** Assume $D = 57, 82$. Let $e < 0$ be a square-free integer for which there exists a point $P \in X_D(\mathbb{Q}(\sqrt{e}))$ such that $\pi_v(P) \in X^{(u)}(\mathbb{Q})$ and let $\alpha$ be either 3 or 2 depending on whether $D$ is equal to 57 or 82. Then, $X^{(v)}$ admits an equation of the form

$$Y^2 = e(x^2 + \alpha)F(x),$$

where $F(x) \in \mathbb{Q}[x]$ is a monic polynomial of degree 4, $\pi_v(F_u)$ is the set of Weierstrass points corresponding to $x = \pm\sqrt{-\alpha}$ and $y^2 = F(x)$ is an equation for $X^{(u)}$ with $w(x, y) = (x, -y)$. For such an equation,

$$y^2 = F(x), \quad t^2 = e(x^2 + \alpha)$$

is an equation for $X_D$.

**Proof.** Since for $D = 57, 82$ we have that $|X^{(u)}(\mathbb{Q})| = \infty$, we can choose two points $P, Q$ in $\pi_u^{-1}(X^{(v)}(\mathbb{Q}))$ such that the sets $\{P, u(P), v(P), w(P)\}$ and $\{Q, u(Q), v(Q), w(Q)\}$ are disjoint. It is clear that both sets are stable by Galois conjugations and each of them has all its points defined in the same imaginary quadratic field.

With the same argument used for $\lambda_1$ in the above proposition, we choose $\nu_2, \nu_3$ in $\pi_u^*(H^1(X^{(v)}, \Omega^{1}_{X^{(v)}/\mathbb{Q}}))$ such that

$$\text{div} \nu_2 = (Q) + (u(Q)) + (w(Q)) + (v(Q)), \quad \text{div} \nu_3 = (P) + (u(P)) + (w(P)) + (v(P)).$$

Set $x = \nu_2/\nu_3$ and $y = dx/\nu_1$. The functions $x$ and $y^2$, viewed as functions on $X_D/(u, v)$, have a unique pole of multiplicity 1 and 4 respectively at the projection of $P$. Therefore,

$$\mathbb{Q}(X^{(u)}/(w)) = \mathbb{Q}(X^{(v)}/(w)) = \mathbb{Q}(x), \quad \mathbb{Q}(X^{(u)}) = \mathbb{Q}(x, y) \quad \text{and} \quad y^2 = F(x),$$

where $F(x) \in \mathbb{Q}[x]$ has degree 4 and $w$ acts by sending $(x, y)$ to $(x, -y)$. Observe that the leading coefficient of $F$ and $F(0)$ are rational squares since the projections of $P$ and $Q$ into $X^{(u)}$ are rational.

Set $t = x/\nu_3 \in \mathbb{Q}(X_D)$. Of course, $u^*(t) = v^*(t) = -t$ and $w^*(t) = t$. In particular $t \not\in \mathbb{Q}(X^{(v)})$ and $t^2 \in \mathbb{Q}(X_D/(u, v))$. Since $t^2$, viewed as a function on $X_D/(u, v)$, has a unique pole of multiplicity 2 at the projection of $P$, $t^2$ is a polynomial of degree 2 in $x$ with rational coefficients. The function $t^2$, now viewed as a function on $X^{(v)}$, has its zeros at the points of $\pi_v(F_u)$, defined over $\mathbb{Q}(\sqrt{-\alpha})$ (see Table 1), and has its poles at the points of $\pi_v(P, u(P))$, defined over $\mathbb{Q}(\sqrt{e})$. Therefore, changing $t$ by $at$ and $x$ by $bx + c$ for a suitable $a, b, c \in \mathbb{Q}$, we can get $t^2 = e(x^2 + \alpha)$. Now, by scaling $y$ by a suitable rational, $F$ can be taken monic. Taking $Y = ty$, we obtain the following equation for $X_D$:

$$X_D: \quad y^2 = F(x) \quad \text{and} \quad t^2 = e(x^2 + \alpha),$$

$$X^{(u)}: \quad y^2 = F(x),$$

$$X^{(v)}: \quad Y^2 = e(x^2 + \alpha)F(x).$$

Set $F(x) = x^4 + ax^3 + bx^2 + cx + d$. Let $T^2 = d(z^2 + \alpha)G(z)$ be any equation for $X^{(v)}/\mathbb{Q}$ such that $\pi_v(F_u)$ corresponds to the set of points with $x = \pm\sqrt{-\alpha}$ and $t^2 = G(z)$ is an equation equivalent to $y^2 = F(x)$. We can assume that the
isomorphism between both equations for $X^{(u)}$ sends $z = \sqrt{-\alpha}$ and $z = -\sqrt{-\alpha}$ to $x = \sqrt{-\alpha}$ and $x = -\sqrt{-\alpha}$ respectively. So, the isomorphism must be of the form

$$(x, Y) = \left( -\frac{\alpha}{z}, \frac{\lambda T}{z^3} \right) \quad \text{or} \quad (x, Y) = \left( \frac{z - \alpha \gamma}{\gamma z + 1}, \frac{\lambda T}{(\gamma z + 1)^3} \right).$$

If $(x, Y) = (-\alpha/z, \lambda T/z^3)$, the condition that the equation $t^2 = G(z) = \alpha \frac{\lambda T}{z^3} F(-\alpha/z) z^4$ is equivalent to $y^2 = F(x)$ leads to the contradiction that $\alpha$ should be a rational square.

If $(x, Y) = ((z - \alpha \gamma)/\gamma z + 1), \lambda T/(\gamma z + 1)^3)$, then $(1 + \alpha \gamma^2)(1 + b \gamma^2 + c \gamma^3 + d \gamma^4) = \lambda^2$.

Moreover, since $t^2 = G(z) = \frac{1}{1 + b \gamma^2 + c \gamma^3 + d \gamma^4} F\left( -\frac{\alpha}{z} \right) z^4$ is equivalent to $y^2 = F(x)$, $1 + b \gamma^2 + c \gamma^3 + d \gamma^4$ is a rational square and, thus, $1 + \alpha \gamma^2 = \beta^2$ for some $\beta \in \mathbb{Q}$. Hence, the change

$$(x, Y, t) = \left( \frac{z - \alpha \gamma}{\gamma z + 1}, \frac{\lambda T}{(\gamma z + 1)^3}, \beta W \right)$$

provides an isomorphism between the equation for $X_D$ given in (4) and the equation $T^2 = G(z)$ and $W^2 = e(z^2 + \alpha)$.

**Remark 3.3.** By the theory of Heegner points, we can take $e = -1$ and $e = -3$ for $D = 59$ and $D = 82$ respectively.

### 4. Equations for Atkin-Lehner quotients and $X_D$

**4.1. Genus one quotients.** Here, we focus our attention on the curve $X^{(u)}$. The Jacobian of the curve $X^{(u)}$ has conductor $D$ because is a quotient of the new part of the Jacobian of $X_0(D)$ defined over $\mathbb{Q}$ and its $\mathbb{Q}$-isomorphism class can be determined by using the Cerednik-Drinfeld description of the fibers of $X_D$ at primes $p | D$ (cf. [17] and the footnote in page 938 of [6]). Next, we show the set $X^{(u)}(\mathbb{Q})$, given as group when $X^{(u)}$ is elliptic over $\mathbb{Q}$, and Cremona’s label of the elliptic curve $\text{Jac}(X^{(u)})$:

**Proposition 4.1.** The following table shows equations for $X^{(u)}/\mathbb{Q}$ of the form $Z^2 = F(X)$, for which the involution $w$ acts sending $(X, Z)$ to $(X, -Z)$:
Proposition 4.4. and equations for all these cases, i.e. for equations por the corresponding quotients. We omit details of these computations

In particular, any equation for \( X^{(u)} \) of the form \( Z^2 = G(X) \) with \( \deg G(X) = 3 \) or 4 for which the action of \( w \) is given by \( (X, Z) \mapsto (X, -Z) \) is equivalent over \( \mathbb{Q} \) to the equation given in Table 2.

**Proof.** When \( X^{(u)}(\mathbb{Q}) = \emptyset \), i.e. for \( D \neq 35, 51, 57 \) and 82, see Theorem 4.2 of [6]. For \( D = 51, 57 \) and 82, we proceed as in [6]. We take a subset \( \{ P_1, \cdots, P_n \} \subset \text{Jac}(X^{(u)})(\mathbb{Q}) \) of representative elements of the group \( \text{Jac}(X^{(u)})(\mathbb{Q})/2 \text{Jac}(X^{(u)})(\mathbb{Q}) \) and for each \( P_i \) we attach an equation \( y^2 = F_i(x) \) as in subsection 2.1 of [6]. The equation in the statement corresponds to the unique equivalence class such that the number field generated by the roots of \( F_i(x) \) agrees with the number field generated by the coordinates of the points in \( \pi_n(F_u) \). Since for \( D = 35 \) this procedure gives two equivalence classes satisfying the before condition, in this case we use another argument. Indeed, from [12] we know that

\[
y^2 = -x(9x + 4)(4x + 1)(172x^3 + 176x^2 + 60x + 7)
\]

is an equation for \( X^{(v)} \) and, moreover, it can be checked that the \( x \)-coordinates of the Weierstrass points coming from \( F_u \) are 0 and \(-4/9\). Since the change

\[
x = \frac{4X}{-9X + 1}, \quad y = \frac{4Y}{(-9X + 1)^3}
\]

provides an isomorphism with the curve \( Y^2 = -X(7X + 1)(X^3 + 197X^2 + 51X + 7) \) sending \( x = 0, -4/9 \) to \( X = 0, \infty \), the equation in Table 2 is obtained by applying part (1) of Proposition 3.1. \( \square \)

4.2. Genus two quotients. Now, we deal with the curve \( X^{(v)} \). Equations for \( D = 35, 51, 57, 69 \) can be found in [12]. Moreover, the procedure used in this paper allows us to determine which Weierstrass points come from fixed points of \( u \). For \( D = 39, 55 \) we can determine equations for \( X^{(v)} \) either following the same procedure used for the before mentioned cases or finding the explicit action of the automorphism \( v \) in the equations presented for \( X_D \) in [12] and determining equations por the corresponding quotients. We omit details of these computations and equations for all these cases, i.e. for \( D \) odd, are presented in Table 4 of Proposition 4.4.
For $D$ even, i.e. $D = 62, 82, 94$, it is harder to find equations for $X^{(v)}$ than for the odd case. We do not have a description of the thicknesses of the singular points in terms of the valuation of the difference of the roots of the polynomials involved in a suitable model of the form $Y^2 = R(X)$ at $p = 2$ (see Theorem 2.3 of [12]). This is basically due to the fact that a model of the form $Y^2 = R(X)$ is not a good model at $p = 2$.

Let $W$ be a model for $X^{(v)}$ over $\mathbb{Z}$ of the form:
\begin{equation}
W : Y^2 + Q(X)Y = P(X), \quad P(X), Q(X) \in \mathbb{Z}[X].
\end{equation}

For such a model, its discriminant is defined as follows:
\[
\Delta(W) = \left\{ \begin{array}{ll}
2^{-12}\text{Disc}(4P(X) + Q(X)^2) & \text{if } \deg(4P(X) + Q(X)^2) = 6, \\
2^{-12}c^2\text{Disc}(4P(X) + Q(X)^2) & \text{if } \deg(4P(X) + Q(X)^2) = 5,
\end{array} \right.
\]
where $c$ is the leading coefficient of $4P(X) + Q(X)^2$. Let $W_0$ be the model with minimal discriminant. The following result due to Q. Liu [10, Théorèmes 1, 2 and Proposition 1] describes the valuation of the discriminant $\Delta(W_0)$ in terms of the canonical model of $X^{(v)}$, its minimal regular model and the exponent of the conductor attached to the Galois representation on the Tate module of its Jacobian. Since the Jacobian of $X^{(v)}$ is isogenous over $\mathbb{Q}$ to an abelian subvariety of $\text{Jac}(X_0(D))^{\text{new}}$, we know by H. Carayol (cf. [2]) that its conductor is $D$ raised to its dimension. Thus the result provides the valuations of the discriminant $\Delta(W_0)$.

**Theorem 4.2.** Let $C$ be a smooth projective geometrically connected curve of genus 2 defined over a finite extension $K$ of $\mathbb{Q}_p$, with integer ring $\mathcal{O}_K$. Let $\mathcal{C}_{\text{can}}/\mathcal{O}_K$ and $\mathcal{C}_{\text{min}}/\mathcal{O}_K$ be its canonical and minimal regular models, respectively. Let us denote by $\sigma$ the extension of the hyperelliptic involution of $C$ to $\mathcal{C}_{\text{can}}$. Let $n$ be the number of irreducible components of the special fiber of $\mathcal{C}_{\text{min}}$ and let $d$ be the number of connected components of the special fiber of the minimal desingularization of $\mathcal{C}_{\text{can}}/\sigma$. Then, the exponent of the conductor $f$ of $C/K$ can be expressed as:

\[
f(C/K) = v(\Delta(W_0)) - 11 \cdot \frac{d - 1}{2} - n + 1,
\]
where $v$ is the normalized valuation of $K$.

Since the conductor of the Jacobian of $X^{(v)}$ is $D$ raised to its dimension, we have $f(X^{(v)}/\mathbb{Q}_p) = 2$ at every prime $p \mid D$. Moreover, the Cerednik-Drinfeld special fiber of $X_D$ at $p \mid D$ can be computed using MAGMA, together with the action of $u$, $v$ and $w$ on its irreducible components and singular points (see [8]). Hence, we are able to compute the special fiber of a semistable model for $X^{(v)}$ and the action of the hyperelliptic involution $w$ on it. Contracting exceptional divisors and next blowing-down and blowing-up singularities, we obtain the special fibers of $\mathcal{C}_{\text{can}}^{(v)}$ and $\mathcal{C}_{\text{min}}^{(v)}$, the canonical and minimal regular models of $X^{(v)}$ respectively, together with the action of the hyperelliptic involution on both of them. Thus, we determine $n$, $d$ and, thus, $v_p(\Delta(W_0))$ at every prime $p \mid D$. Using this procedure we obtain the following result.

**Proposition 4.3.** The absolute values of the discriminants $\Delta(W_0)$ of the minimal hyperelliptic models $W_0/\mathbb{Z}$ of $X^{(v)}$ are given by the following table:

<table>
<thead>
<tr>
<th>$D$</th>
<th>$\Delta(W_0)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>2 $\cdot$ 31</td>
<td>$2^{15} \cdot 31^4$</td>
</tr>
<tr>
<td>2 $\cdot$ 41</td>
<td>$2^{15} \cdot 41^4$</td>
</tr>
<tr>
<td>2 $\cdot$ 47</td>
<td>$2^{19} \cdot 47^2$</td>
</tr>
</tbody>
</table>
Proof. We compute the valuation of $\Delta(W_0)$ at every prime of bad reduction using the above theorem and the procedure, described in the previous paragraph, to compute the special fibers of $X_{\text{can}}^{(v)}$ and $X_{\text{min}}^{(v)}$ together with the action of the hyperelliptic involution on both of them. We show this procedure for the three even values of $D$ and $p = 2$.

**Case 4.1.** For $D = 94$ and $p = 2$, we compute the special fiber of $X_D$ using Cerednik-Drinfeld theory. We describe graphically the quotients, contractions of exceptional divisors, blown-ups and blow-downs we have apply to obtain the special fibers of $X_{\text{can}}^{(v)}$ and $X_{\text{min}}^{(v)}$:

We obtain that the number of irreducible components of the special fiber of the minimal regular model is $n = 18$ and, moreover, the number of connected components of the special fiber of the minimal desingularization of $X_{\text{can}}^{(v)}/w$ is $d = 1$. Thus, we get $\nu_2(\Delta(W_0)) = 19$.

**Case 4.2.** The case $D = 62$ and $p = 2$ is similar to the previous case. We obtain that the number of irreducible components of the special fiber of the minimal regular model is $n = 14$. Moreover, the number of connected components of the special fiber of the minimal desingularization of $X_{\text{can}}^{(v)}/w$ is also $d = 1$. Thus, we get $\nu_2(\Delta(W_0)) = 15$.

**Case 4.3.** For $D = 82$ and $p = 2$, we have the following special fibers:
We obtain that the number of irreducible components of the special fiber of the minimal regular model is $n = 3$ and, moreover, the number of connected components of the special fiber of the minimal desingularization of $X^{(v)}_{\text{can}}/w$ is $d = 3$. Thus, we get $\nu_2(\Delta(W_0)) = 15$.

The computation of the valuations $\nu_p(\Delta(W_0))$ provides $\Delta(W_0)$ up to sign, namely, the absolute value $|\Delta(W_0)|$. □

From $W_0$, we obtain a model $W'_0$ of the form $Y^2 = R(X) = 4P(X) + Q^2(X)$. Note that $\Delta(W_0)$ provides the discriminant of $R(X)$. The roots of $R(X)$ are the $X$-coordinates of the Weierstrass points of $X^{(v)}$, i.e. $\pi_v(F_w) \cup \pi_v(F_u)$. In Table 1, it is given the field of definition $L_u$ of the coordinates of any $U \in \pi_v(F_u)$. Again by using [6], the fields of definition $L_w$ of the coordinates of any $W \in \pi_v(F_w)$ are:

<table>
<thead>
<tr>
<th>$D$</th>
<th>$L_w = \mathbb{Q}(W)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$2 \cdot 31$</td>
<td>$\mathbb{Q}[X]/(X^4 + X^3 + 4X^2 - 2X + 4)$</td>
</tr>
<tr>
<td>$2 \cdot 41$</td>
<td>$\mathbb{Q}[X]/(X^4 + 2X^3 - X^2 - 2X + 2)$</td>
</tr>
<tr>
<td>$2 \cdot 47$</td>
<td>$\mathbb{Q}[X]/(X^2 + 5X^2 + 18)$</td>
</tr>
</tbody>
</table>

Table 3.

Note that $L_u$ and $L_w$ are the fields involved in the factorization of $R(X) = \prod_i \nu_i(X)$. The above analysis of the special fibers provides

$$\text{Disc}(R) = \prod_i \text{Disc}(\nu_i) \prod_{i,j} \text{Res}(\nu_i, \nu_j)^2.$$
By using specialization of Heegner points we can determine the valuations of \( \text{Disc}(p_i) \) and \( \text{Res}(p_i, p_j) \) at every odd prime (see §4 of [12]). Since we know the 2-valuation of \( \text{Disc}(R) \), we have a finite number of possible 2-valuations for \( \text{Disc}(p_i) \). Moreover, its sign is determined by the field of definition of \( p_i \). A suitable choice of the points at infinity (they are going to be also Heegner points), provides the leading coefficients of the \( p_i \).

Once we know the leading coefficient \( c_i \), we proceed to determine the corresponding monic polynomial \( q_i(X) = c_i^{\deg p_i} p_i(X/c_i) \in \mathbb{Z}[X] \), whose discriminant is \( \text{Disc}(q_i) = c_i^{\deg p_i\cdot 2} \text{Disc}(p_i) \). By [7], there are only finitely many monic polynomials with integer coefficients, up to translation by integers, with the same discriminant and field of definition as \( q_i \). Let \( L_i \) be the field of definition of \( p_i \) and let \( \mathcal{O}_{L_i} \) be its integer ring, let \( \alpha_i \in \mathcal{O}_{L_i} \) be a root of \( q_i \). Since the discriminant of \( q_i \) provides the index of the order \( \mathbb{Z}[[\alpha_i]] \) in \( \mathcal{O}_i \), by means of the instruction \text{IndexFormEquation} of MAGMA, we determine a finite number of candidates for \( \alpha_i \) and \( p_i \) up to translation by integers. For any of these choices for all \( i \), we determine \( R(x) \) by using that \( \text{Res}(p_i, p_j) \) is known. Next, we will use properties of Shimura curves to discard fake equations in case that our procedure produces more than one candidate.

### 4.2.1. Computing equations

The cases \( D = 62 \) and 94 are similar and correspond to type 1 introduced in section 3. In both cases the pair of Weierstrass points coming from the fixed points of \( u \) are rational. We choose one of these rational Weierstrass points to be the point of infinity. Therefore the model \( \mathcal{W}'_0 \) is given by

\[
\mathcal{W}'_0 : Y^2 = R(X) = \pm p_1(X) \cdot p_2(X),
\]

where \( p_1 \) is the polynomial of degree 1 corresponding to the other rational point and \( p_2 \) is the irreducible polynomial corresponding the Galois orbit \( \pi_u(\mathcal{F}_w) \) with field of definition \( L_w \). Recall that \( \Delta(\mathcal{W}_0) = 2^{-12}c^2 \text{Disc}(R) \) is given, where \( c \) is the leading coefficient of \( R \). For the case \( D = 62 \), we have \( \Delta(\mathcal{W}_0) = 2^{15}31^4 \) while for \( D = 94 \), \( \Delta(\mathcal{W}_0) = 2^{19}47^2 \). By the results on the reduction of Heegner points (cf. [13], [12]), we can compute the valuation of \( \text{Disc}(p_2) \) at every odd prime. Set \( \nu_2(\text{Disc}(p_2)) = t \), we computed

\[
\text{Disc}(p_2) = \begin{cases} 2^431^4, & \text{if } D = 62, \\ 2^247^2, & \text{if } D = 94. \end{cases}
\]

Since \( \text{Disc}(R) = \text{Disc}(p_2) \text{Res}(p_1, p_2)^2 \), we obtain that \( c \) and \( \text{Res}(p_1, p_2) \) are powers of 2. Therefore,

\[
\begin{align*}
\{ & p_1(X) = 2^\alpha X + b, \\
& p_2(X) = 2^\gamma X^4 + dX^3 + eX^2 + fX + g,
\end{align*}
\]

(6) \( \text{Disc}(p_2) \text{Res}(p_1, p_2)^2 = 2^{12}c^{-2}\Delta(\mathcal{W}_0) = \begin{cases} 2^{27}2^{-2\alpha-2\gamma}31^4 & \text{if } D = 62, \\ 2^{31}2^{-2\alpha-2\gamma}47^2 & \text{if } D = 94, \end{cases} \)

(7) \( \alpha + \gamma \leq \frac{12 + \nu_2(\Delta(\mathcal{W}_0))}{2}; \quad \alpha + \gamma \leq \begin{cases} 13 & \text{if } D = 62, \\ 15 & \text{if } D = 94. \end{cases} \)

First we compute the polynomial \( p_2 \). Notice that

(8) \( t \leq 12 + \nu_2(\Delta(\mathcal{W}_0)) - 2\alpha - 2\gamma = \begin{cases} 27 - 2\alpha - 2\gamma & \text{if } D = 62, \\ 31 - 2\alpha - 2\gamma & \text{if } D = 94. \end{cases} \)
Instead of determining the polynomial $p_2(X)$, we determine the corresponding monic polynomial with integer coefficients

$$q_2(X) = 2^{3\gamma}p_2(X/2^\gamma) = X^4 + dX^3 + 2^{3\gamma}eX^3 + 2^{2\gamma}fX^2 + 2^{3\gamma}g$$

with $\text{Disc}(q_2) = 2^{6\gamma}\text{Disc}(p_2)$. We do not know explicitly $\nu_2(\text{Disc}(q_2))$, but we can bound it thanks to (7) and (8):

$$\nu_2(\text{Disc}(q_2)) = t + 6\gamma \leq 12 + \nu_2(\Delta(W_0)) + 4\gamma \leq 36 + 3\nu_2(\Delta(W_0)).$$

Since $q_2$ is monic and defines the field $L_w$ given in Table 2, we have $\text{Disc}(q_2) = N^2\text{Disc}(L_w)$, where $N \in \mathbb{Z}$ is the index. It is known that there are finitely many possible $q_2$ for a given $N$ and $L_w$, up to translation by integers. In our case, $N = 2^m$ and, moreover, $m$ is bounded since $\nu_2(\text{Disc}(q_2)) \leq 36 + 3\nu_2(\Delta(W_0))$.

By means of the instruction $\text{IndexFormEquation}$ of $\text{MAGMA}$, we compute all the possible values of $m$ which provide candidates for $q_2$. We obtain

$$\begin{array}{c|c}
D & m \\
\hline
62 & 3, 9, 12, 15, 18, 21, 24 \\
94 & 3, 6, 9, 12, 15, 18, 21, 24, 27 \\
\end{array}$$

Notice that $2m + \nu_2(\text{Disc}(L)) = \nu_2(\text{Disc}(q_2)) = t + 6\gamma$ and, thus,

$$\gamma \leq \frac{2m + \nu_2(\text{Disc}(L))}{6}.$$

This inequality provides a finite number of possibilities for the leading coefficient $2^\gamma$ for a fixed $q_2$. Among all possibilities for the pairs $(q_2, \gamma)$, we select those for which there is an integer $s$ in a set of representatives modulo $2^\gamma$ such that $p_2(x) = 2^{-3\gamma}q_2(2^\gamma x + s)$ has integer coefficients and, moreover, $\nu_2(\text{Disc}(p_2)) \leq 12 + \nu_2(\Delta(W_0)) - 2\gamma$. Finally, we obtain 17 possibilities for $p_2$ if $D = 62$ and 68 if $D = 94$.

Recall that

$$\text{Res}(p_1, p_2)^2 = 2^{8\alpha}p_2(-b/2^\alpha)^2 = 2^{12}2^{2\alpha-2\gamma}\text{Disc}(p_2)^{-1}\Delta(W_0).$$

Thus, $\alpha \leq (12 - 2\gamma - \nu_2(\text{Disc}(p_2)) + \nu_2(\Delta(W_0)))/2 := r$. Now, for a given $p_2$ and $a$ in the range $[0, \ldots, r]$, we select the pairs $(p_2, a)$ such that the equation $p_2(x) = \pm 2^{a-5\alpha}$ admits the rational solution $-b/2^\alpha$. For each of such pairs, we have two possible equations for $X^{(v)}$: $Y^2 = \pm(2^aX + b)p_2(X)$.

In the case $D = 62$, we obtain 6 possible solutions up to $\mathbb{Q}$-isomorphisms:

$$\begin{align*}
(C_1^+) & \quad Y^2 = (X + 6)(X^4 + 6X^3 + 27X^2 + 116X + 236), \\
(C_1^-) & \quad Y^2 = -(X + 6)(X^4 + 6X^3 + 27X^2 + 116X + 236), \\
(C_2^+) & \quad Y^2 = (X + 3)(4X^4 + 12X^3 + 27X^2 + 58X + 59), \\
(C_2^-) & \quad Y^2 = -(X + 3)(4X^4 + 12X^3 + 27X^2 + 58X + 59), \\
(C_3^+) & \quad Y^2 = X(64X^4 + 99X^3 + 90X^2 + 43X + 8), \\
(C_3^-) & \quad Y^2 = -X(64X^4 + 99X^3 + 90X^2 + 43X + 8).
\end{align*}$$

By using the instruction $\text{genus2reduction}$ of $\text{SAGE}$, we determine the type of reduction modulo $p = 2$ of these curves. We obtain that $(C_1^+)$, $(C_1^-)$, $(C_2^+)$ and $(C_2^-)$ have stable reduction of type $V$, while $(C_3^+)$ and $(C_3^-)$ have stable reduction of type $IV$ with the Liu notation (cf. [11]). Since $X^{(v)}$ have stable reduction of type $IV$ at $p = 2$, our candidates are now $(C_3^+)$ and $(C_3^-)$. 

Since Jac($X_{62}$) is isogenous over $\mathbb{Q}$ to Jac($X_0(62)_{\text{new}}$) and this abelian variety is isogenous over $\mathbb{Q}$ to the product of an elliptic curve and a simple abelian surface, there is a normalized newform $f = q + \sum_{n>1} a_n q^n \in S_2(\Gamma_0(62))$ such that the abelian surface $A_f$ attached to $f$ by Shimura is isogenous over $\mathbb{Q}$ to Jac($X^{(v)}$). One has that $\mathbb{Q}(\{a_n\}) = \mathbb{Q}(\sqrt{3})$ and, moreover, $a_3 = 1 + \sqrt{3}$. Applying the Eichler-Shimura congruence, we know that the trace of the Frobenius automorphism $\text{Frob}_p$ acting on the $\ell$-adic ($\ell \neq 3$) Tate module of the reduction of Jac($X^{(u)}$) mod 3 is equal to $a_3$ plus its Galois conjugate, i.e. 2. An easy computation allows us to discard the equation $C_3^{(v)}$ and we obtain that $X^{(v)}$ has the following equation

$$X^{(v)}: \quad Y^2 = -X(64X^4 + 99X^3 + 90X^2 + 43X + 8).$$

In the case $D = 94$, we only obtain two possibilities up to $\mathbb{Q}$-isomorphisms:

- $(C_1^+)$ $Y^2 = (X + 3)(8X^4 + 27X^3 + 45X^2 + 24X + 4),$
- $(C_1^-)$ $Y^2 = -(X + 3)(8X^4 + 27X^3 + 45X^2 + 24X + 4).$

Now, the corresponding normalized newform $f$ of level 94 attached to Jac($X^{(v)}$) is $f = q - q^2 + \cdots + (-2 - 2\sqrt{2})q^7 + \cdots$ and, thus, the trace of $\text{Frob}_7$ is $-4$. We conclude that $X^{(v)}$ has the following equation

$$X^{(v)}: \quad Y^2 = -(X + 3)(8X^4 + 27X^3 + 45X^2 + 24X + 4).$$

The case $D = 82$ corresponds to type 3 and, thus, is slightly different to the above cases. In this case, $X^{(v)}$ does not have any rational Weierstrass point. Let $\{P_\infty, \bar{P}_\infty\}$ be the image, under $\pi_v$, of the set of Heegner points with CM by $\mathbb{Z}[1 + \sqrt{-11}]$. Since such order has class number 1, by [6] we know that $P_\infty$ and $\bar{P}_\infty$ lie in $X^{(v)}(\mathbb{Q}(\sqrt{-11}))$ and the hyperelliptic involution acts on these points as the complex conjugation mapping $P_\infty$ to $\bar{P}_\infty$. We choose $P_\infty, \bar{P}_\infty$ to be our infinity points in the hyperelliptic model.

Let $c$ be the leading coefficient of the equation $Y^2 = R(X)$ of $\mathcal{W}_0'$, once we have chosen the infinity points to be $P_\infty$ and $\bar{P}_\infty$. It is clear that $c = -11N^2$ for some $N \in \mathbb{Z}$. In §6 of [12], it is computed the valuation of $c$ at every $p \nmid D$ in terms of the moduli interpretation of $X_D/\mathbb{Q}$ and its Morita's integral model $X_D/\mathbb{Z}[1/D]$ as spaces that classify abelian surfaces with quaternionic multiplication. Since $\mathcal{W}_0'$ has good reduction outside $D$, it is isomorphic to $X_D$ locally at these primes. This provides an interpretation of the valuation of $c$ at every $p \nmid D$ in terms of the CM abelian surfaces attached to $P_\infty$ and $\bar{P}_\infty$. Applying formulas of Theorem 6.4 in [12], we obtain that $v_p(c) = 0$ for all $p \nmid 11 \cdot D$ and $v_{11}(c) = 1$.

To analyze the case $p \mid D$, we return to the integer model $\mathcal{W}_0$: $Y^2 + Q(X)Y = P(X)$, where $R(X) = Q(X)^2 + 4P(X)$. Note that $P_\infty$ lives in the affine open defined by $v^2 + Q_1(u)v = P_1(u)$, where $Q_1(u) = u^3Q(1/u)$ and $P_1(u) = u^6P(1/u)$. More precisely, $P_\infty$ and $\bar{P}_\infty$ corresponds to the points $(u, v) = (0, \pm\sqrt{c})$. Thus, if $p \mid c$ then both infinity points specialize to a single Weierstrass point. Using the results of [13], we determine that all Weierstrass points have singular specialization at every $p \mid D$. Thus, if $p \mid D$ and $p \nmid c$ then $P_\infty$ specializes to a singular point in $\mathcal{W}_0$.

Any model $\mathcal{W}_0$ as in (5) satisfies that $\mathcal{W}_0/\omega$ is smooth. Moreover one can see that, locally at $p$, such a model $\mathcal{W}_0$ with minimal discriminant can be obtained by normalizing in $X^{(v)}$ any of the irreducible components of $(\mathcal{X}_{\text{can}}/\omega)_p$. Thus if we show that $P_\infty$ lies in a non-singular point of any of the irreducible components
of \( (\mathcal{X}_{\text{can}})^{(v)}_p \), we will conclude that there exists a model \( \mathcal{W}_0 \) such that \( P_\infty \) has good reduction in it.

By Theorem 1.1 of [13], we know that the elements of the set \( \pi_p^{-1}(P_\infty \cup \overline{P}_\infty) \) have non-singular specialization in the Cerednik-Drinfeld special fiber and we have a description of the irreducible components were these points lie. Using this computation we check that, even contracting exceptional divisors and blowing-down singularities (see Case 4.3), \( P_\infty \) and \( \overline{P}_\infty \) have non-singular specialization in \( (\mathcal{X}_{\text{can}})^{(v)}_p \) where \( p | D \). Thus, if we choose a suitable model \( \mathcal{W}_0 \), the infinity point \( P_\infty \) has good reduction at \( p | D \), which implies that \( c = -11 \).

Recall that, since the set of Weierstrass points consists of the pair of Galois orbits \( \pi_v(F_u) \) and \( \pi_v(F_u) \), an equation for \( \mathcal{W}_0 \) is of the form \( Y^2 = R(X) = p_u(X)p_w(X) \), where \( p_u \) determines \( L_u \) and \( p_w \) determines \( L_w \). By means of the results of [13] and [12] on the supersingular specialization of Heegner points, we can determine which Weierstrass points reduce to the specialization of \( P_\infty \) at \( p = 11 \). We obtain that the only Weierstrass point that reduces to the specialization of \( P_\infty \) in \( \pi_v(F_u) \). This fact implies that the leading coefficients of \( p_u \) and \( p_w \) are \(-11 \) and \( 1 \) respectively. Thus, \( p_u(X) = X^4 + cX^3 + dX^2 + eX + f \), \( p_u(X) = -11X^2 + aX + b \) and, moreover, \( \text{Disc}(R) = \text{Disc}(p_u)\text{Disc}(p_w)\text{Res}(p_u,p_w)^2 = 41^7 \cdot 2^{27} \). As in the previous cases, we computed that \( \text{Disc}(p_u) = 41 \cdot 2^{t_u} \), where \( t_u \leq 24 \) because \( \text{Disc}(L_u) = 2^3 \). Since \( p_w \) determines \( L_w \), we computed by means of the instruction \text{IndexFormEquation} that the only possibilities for \( t_u \) are 4, 6, 10 and 12, and we have 8 possible monic polynomials \( p_w \), up to translation. By a similar computation we obtain 6 possibilities for \( p_u \) with \( \text{Disc}(p_u) = 2^{t_u} \). On the other hand, we know that

\[
\text{Res}(p_w(X + \alpha), p_u(X)) = \pm 41^3 \cdot 2^{(27-t_u-t_w)/2}
\]

for some \( \alpha \in \mathbb{Z} \). Selecting all pairs \( (p_u, p_w) \) for which the above equality admits an integer solution \( \alpha \), we obtain 4 possibilities and, hence, 4 equations for the curve \( X^{(v)} \), that turn to be isomorphic. Thus, we obtain the following equation for \( X^{(v)} \):

\[
X^{(v)}: Y^2 = -(11X^2 - 40X + 48)(X^4 - 6X^3 + 13X^2 - 8X + 4).
\]

Observe that for the equations presented for \( X_D \) when \( D = 62, 82 \) and 94, the Weierstrass points coming from fixed points of the involution \( u \) are those whose \( X \)-coordinates are rational or \( \infty \) for \( D = 62 \) and 94, or lie in \( \mathbb{Q}(\sqrt{-2}) \) for \( D = 82 \).

**Proposition 4.4.** Equations for the genus two curves \( X^{(v)} \) together with the coordinates of the two points of \( \pi_v(F_u) \) are given in the following table:

<table>
<thead>
<tr>
<th>( D )</th>
<th>( X^{(v)} )</th>
<th>( \pi_v(F_u) )</th>
</tr>

<td>$y^2 = -3(x^2 + 2)(16x^4 - 32x^3 + 1032x^2 + 1576x - 1549)$, $t^2 = -3(x^2 + 2)$</td>
</tr>
</tbody>
</table>

*Table 5.*

**Remark 4.1.** In Table 1 of [9], Kurihara conjectured equations for all Shimura curves $X_D$ with $D \leq 65$ and genus $> 1$. The six equations in Table 5 with $D \leq 62$ are according to the presented in [9].

5. The kernel of Ribet’s isogeny

We recall that an abelian variety $A$ over a field $K$ if there is a surjective morphism $\pi : A \rightarrow B$ defined over $K$ with connected kernel. In such a case, if $K$ is a subfield of $C$, $B$ is determined by the $K$-vector space $\pi^*(\Omega^1_{B/K})$ and a complex torus for $B$ is obtained by fixing a basis $\omega_1, \cdots, \omega_n$ of $\pi^*(\Omega^1_{B/K})$ and taking the lattice $\{(\int_{\gamma} \omega_1, \cdots, \int_{\gamma} \omega_n) : \gamma \in H_1(A, \mathbb{Z})\}$. Note that the property of being optimal quotient over $K$ has the transitive property.

In the modular case, the assigment $h(q) \mapsto h(q) dq/q$, where $q = e^{2\pi i z}$, yields a bijection between the $C$-vector spaces $S_2(\Gamma_0(N))$ and $\Omega^1_{\Gamma_0(N)/C}$ and, moreover, $\Omega^1_{\Gamma_0(N)/C}$ corresponds to the $Q$-vector space of cuspidal newforms in $S_2(\Gamma_0(N))$ with rational $q$-expansion, i.e. $S_2(\Gamma_0(N)) \cap \mathbb{Q}[q]$. The abelian variety $\text{Jac}(X_0(N))^{\text{new}}$ denotes the optimal quotient of $\text{Jac}(X_0(N))$ over $\mathbb{Q}$ corresponding to the $Q$-vector space $S_2(\Gamma_0(N))^{\text{new}} \cap \mathbb{Q}[q]$ and for a normalized newform $f$ of level $N$, $A_f$ shall denote the optimal quotient of $\text{Jac}(X_0(N))^{\text{new}}$ over $\mathbb{Q}$ determined by the $Q$-vector space of cuspidal newforms with rational $q$-expansion in the $C$-vector space generated by all Galois conjugates of $f$.
Assume that the Shimura curve $X_D$ has genus three and set $A_3 := \text{Jac}(X_0(D))^{\text{new}}$. Since $\text{Jac}(X_D)$ is isogenous over $\mathbb{Q}$ to $A_3$, there are exactly three normalized newforms $f_1$, $f_2$ and $f_3$ in $S_2(\Gamma_0(D))^{\text{new}}$. Let $f_1$ be such that $A_1 := \text{Jac}(f_1)$ is isogenous over $\mathbb{Q}$ to $\text{Jac}(X(u))$. Let $A_2$ be the optimal quotient of $A_3$ such that it is isogenous over $\mathbb{Q}$ to $\text{Jac}(X(v))$. For $D \neq 57$, $A_2 = A_{f_2}$ and $f_3$ is the Galois conjugate of $f_2$. For $D = 57$, $A_2$ is isogenous over $\mathbb{Q}$ to the product $A_{f_2} \times A_{f_3}$, where $A_{f_2}$ and $A_{f_3}$ are non-isogenous elliptic curves over $\mathbb{Q}$ of conductor 57.

Due to the fact that $D$ is the product of two primes $p_1$ and $p_2$, $X_0(D)$ has exactly 4 cusps: 0, 1, $p_1$, $p_2$ and $\infty$. Since $D$ is square-free, all of them are rational points and the following cuspidal divisors

$$D_\infty = (0) - (\infty), \quad D_{p_1} = (0) - (1/p_1), \quad D_{p_2} = (0) - (1/p_2)$$

are torsion points in $\text{Jac}(X_0(D))^{\text{new}}(\mathbb{Q})$ because a multiple of each of them is the divisor of a function in $\mathbb{Q}(X_0(D))$ obtained as product of integer powers of $\eta$-functions (for instance, see [3]). Hence, they generate a finite subgroup $G$ of $\text{Jac}(X_0(D))^{\text{new}}(\mathbb{Q})$ and each element of $G$ provides a rational torsion point in any quotient of $\text{Jac}(X_0(D))$ defined over $\mathbb{Q}$ that will be denoted by the same notation. Let $G_3, G_2$ and $G_1$ be the groups generated by all these divisors in $A_3, A_2$ and $A_1$ respectively. We can view $G_i$ as a finite subgroup of $H_1(A_i, \mathbb{Z}) \otimes \mathbb{Q}/H_1(A_i, \mathbb{Z})$. By fixing a basis of regular differentials of $A_i$, we can determine the groups $G_3, G_2$ and $G_1$. In Table 6 of the Appendix, we present a description of all of them.

In our strategy to determine a subgroup $c(D)$ of $G_3$ such that $\text{Jac}(X_0(D))^{\text{new}}/c(D)$ is $\text{Jac}(X_D)$, an important ingredient is finding a subgroup $G'$ of $G_2$ such that $A_2/G'$ is the jacobian of a genus two curve defined over $\mathbb{Q}$. To do that, we will need to have a polarization on $A_2$ defined over $\mathbb{Q}$ to apply the procedure used in [4]. In order to get such a polarization, we will proceed as follows. We will determine the abelian subvariety $A'_2$ of $\text{Jac}(X_0(D))$ isogenous over $\mathbb{Q}$ to $A_2$ and stable under Hecke operators. Hence, $\pi(A'_2) = A_2$, where $\pi : \text{Jac}(X_0(N)) \to A_2$ is the natural projection. The action of the Riemann form corresponding to the canonical polarization on $\text{Jac}(X_0(D))$ restricted to $H_1(A'_2, \mathbb{Z})$ provides a polarization on $A'_2$ defined over $\mathbb{Q}$. Determining $\pi^{-1}_*(H_1(A_2, \mathbb{Z}))$ as a subgroup of $H_1(A_2, \mathbb{Z}) \otimes \mathbb{Q}$, we will obtain a polarization on $A_2$ defined over $\mathbb{Q}$.

**Theorem 5.1.** With the above notation, there is a subgroup $c(D)$ of $G_3$ which is the kernel of an isogeny $\Phi : \text{Jac}(X_0(D))^{\text{new}} \to \text{Jac}(X_D)$ defined over $\mathbb{Q}$. The following table shows $c(D)$ for each of these values $D$:

<table>

**Proof.** Let $\{h_1, h_2, h_3\}$ be a basis of $S_2(\Gamma_0(D))^{\text{new}}$ with rational $q$-expansion such that $h_1 = f_1$ and $\{h_2, h_3\}$ is a basis of the vector space generated by $f_2$ and $f_3$. Let $\Omega_{c(D)}$ be a period matrix for $\text{Jac}(X_0(D))^{\text{new}}/c(D)$ corresponding to this basis and a basis of the $\mathbb{Z}$-module $H_1(A_3, \mathbb{Z}) \otimes \mathbb{Q}$, where $c(D)$ is as in the statement. For a fixed basis of $\Omega_{X_D/\mathbb{Q}}^L$, let us denote by $\Omega_{sh}$ a period matrix for $\text{Jac}(X_D)$ with respect this basis. The statement amounts to prove that there are two matrices $C \in \text{GL}_3(\mathbb{Q})$ and $M \in \text{GL}_6(\mathbb{Z})$ with $\det(M) = \pm 1$ satisfying

$$\Omega_{c(D)} \cdot M = C \cdot \Omega_{sh}.$$
For $X_D$, we take the equation $y^2 = f(x)$ given in Table 5 of Theorem 4.5. Let $Z^2 = F(X)$ and $Y^2 = H(X)$ be the corresponding equations presented for $X^{(u)}$ and $X^{(v)}$ respectively in Table 4 of Proposition 4.4. For any subgroup $G'_3$ of $G_3$, let us denote by $G'_2$ and $G'_1$ its projections in $G_2$ and $G_1$ respectively.

Since the proof will be done computationally, we have to take care with mistakes coming from numerical approximations. For this reason, our procedure is based on the two following facts. On the one hand, we shall determine a quotient of $A_1$ coming from numerical approximations. For this reason, our procedure is based on the other hand, to compute $\Omega_{sh}$ we shall choose the following basis of $\Omega^1_{X_D/Q}$:

$$\{\omega_1, \omega_2, \omega_3\} = \{\pi_i^*(dX/Z), \pi_i^*(dX/Y), \pi_i^*(X \, dX/Y)\}.$$  

In this way, the matrix $C$ as in (9) should be of the following form

$$C = \begin{pmatrix} * & 0 & 0 \\ 0 & * & * \\ 0 & * & * \end{pmatrix} \in \text{GL}_3(\mathbb{Q}).$$

We sketch the proof by splitting the procedure used in the following steeps:

(i) Compute period matrices $\Omega_3$, $\Omega_2$ and $\Omega_1$ for $A_3$, $A_2$ and $A_1$ with respect the bases $\{h_1(q)d/q, h_2(q)d/q, h_3(q)d/q\}$ and $h_1(q)d/q$ respectively.

(ii) For every $i \leq 3$, determine the coordinates of $D_{\infty}, D_{p_1}$ and $D_{p_2}$ with respect the bases of the homologies $H_1(A_i, \mathbb{Z})$ used for computing the period matrices $\Omega_i$, $1 \leq i \leq 3$.

(iii) Find a subgroup $G'$ of $G_2$ such that $A' = A_2/G'$ has an irreducible principal polarization over $\mathbb{Q}$. Take a basis for $G' + H_1(A_2, \mathbb{Z})$ and let $\Omega'_{G_2}$ be a period matrix with respect this basis and the same basis of regular differentials used to compute the matrix $\Omega_{G_2}$. Following the procedure used in 4.6 of [4], compute a genus two curve $C : y^2 = r(x)$ such that Jac($C$) = $A'$ (if possible, take $G'$ such that $C$ is isomorphic over $\mathbb{Q}$ to $X^{(v)}$). Observe that using this procedure, the matrix $\Omega'_{G_2}$ is a matrix period for Jac($C$) with respect the basis $\{dx/y, x \, dx/y\}$. For instance,

</tbody>
</table>
(iv) Compute a period matrix $\Omega_{sh2}$ for $X^{(v)}$ with respect the basis $dX/Y, X \, dX/Y$ and determine a matrix $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}_2(\mathbb{Q})$ for which there exists a matrix $M_2 \in \text{GL}_4(\mathbb{Z})$ such that

$$\Omega'_{2} \cdot M_2 = A \cdot \Omega_{sh2} .$$

In order to do that, we can use the instruction IsIsogenousPeriodMatrices of the program MAGMA to determine these matrices. When $C$ is isomorphic to $X_v$, the explicit isomorphism between both curves provides the matrices $A$ and $M_2$.

(v) Let $\mathcal{G}'_3$ be a subgroup of $\mathcal{G}_3$ such that $\mathcal{G}'_2 = \mathcal{G}'$. Let $\Omega'_1$ be a period matrix of $A_1/\mathcal{G}'_1$ with respect the basis $h_1(q)dq/q$. Compute a period matrix $\Omega_{sh1}$ for $X^{(u)}$ with respect $dX/Z$ and determine a rational $m$ for which there exists a matrix $M_1 \in \text{GL}_2(\mathbb{Z})$ such that

$$\Omega'_1 \cdot M_1 = m \cdot \Omega_{sh1} .$$

(vi) Compute a period matrix $\Omega_{sh}$ with respect to the basis $\omega_1 = \pi^*_v(dX/Z), \omega_2 = \pi^*_v(dX/Y), \omega_3 = \pi^*_v(X \, dX/Y)$ of $\Omega^1(X_D)$. Observe that for $D \neq 57, 82$ one has that

$$\begin{pmatrix} 2x \, dx/y, 2dx/y, 2x^2 \, dx/y \\ ((x^2 + 1) \, dx/y, x \, dx/y, (x^2 - 1) \, dx/y \end{pmatrix} \text{ if } D \in \{35, 51, 62, 69, 94\},$$

$$\begin{pmatrix} (2x^2 \, dx/y, 2dx/y, 2x^2 \, dx/y \\ ((x^2 + 1) \, dx/y, x \, dx/y, (x^2 - 1) \, dx/y \end{pmatrix} \text{ if } D \in \{39, 55\}.$$  

For $D = 57, 82$, we have that $H(X) = e(X^2 + \alpha) \text{F}(X)$ and $Y = Z \, t$. Setting $u = t/(X + \sqrt{-\alpha})$, with the change

$$X = -\sqrt{-\alpha} \frac{u^2 + e}{u^2 - e}, \quad z = \frac{(u^2 - e)^3 \, Z \, t}{u},$$

we obtain the hyperelliptic model defined over $\mathbb{Q}(\sqrt{-\alpha})$ for $X^{(v)}$

$$z^2 = f(u) = \frac{(u^2 - e)^6}{u^2} H \left( -\sqrt{-\alpha} \frac{u^2 + e}{u^2 - e} \right),$$

which allows us to compute a matrix period for this equation with respect the basis of regular differentials $\{du/z, \frac{udu}{z}, \frac{udu}{z}, \frac{udu}{z} \}$. In this case

$$\begin{pmatrix} 8 \, e^2 \alpha \, u \, du/z, 4 \, e \sqrt{-\alpha} \left( \frac{u^2 \, du}{z} - e \frac{du}{z} \right), 4 \, e \alpha \left( \frac{u^2 \, du}{z} + e \frac{du}{z} \right) \end{pmatrix} .$$

(vii) Determine an integer $\lambda$ for which there is a matrix $M' \in \text{GL}_6(\mathbb{Z})$ such that

$$\Omega_{c(D)} \cdot M' = \lambda \cdot A' \cdot \Omega_{sh} , \quad \text{where } A' = \begin{pmatrix} m & 0 & 0 \\ 0 & a & b \\ 0 & c & d \end{pmatrix} .$$

(viii) By using the Hermite decomposition of the matrix $M'$ and the action of $\text{End}_q(A_3/c(D))$ on $\Omega_{c(D)}$, we can find an endomorphism $\phi \in \text{End}_q(A_3/c(D))$ whose action on the basis $\{h_1, h_2, h_3\}$ is given by a matrix $B \in \text{GL}_2(\mathbb{Q})$ and for which

$$B \cdot \Omega_{c(D)} \cdot M = \Omega_{c(D)} \cdot M' ,$$

for some $M \in \text{GL}_6(\mathbb{Z})$ with det$(M) = \pm 1$. Finally, putting $C = \lambda \cdot B^{-1} \cdot A'$ we obtain that

$$\Omega_{c(D)} \cdot M = C \cdot \Omega_{sh} .$$
In Table 7 of the Appendix, we show the cusp forms $h_2$ and $h_3$ used in our computation, by giving the first terms of their $q$-expansions, and the matrix $C$ obtained. The matrix $M$ is omitted, since it depends on the chosen bases for the homologies of $\text{Jac}(X_0(D))^{\text{new}}/c(D)$ and $\text{Jac}(X_D)$. \hfill \Box
