Abstract

In this paper, the flutter behaviour of functionally graded material plates immersed in a supersonic flow is studied. An enriched 4-noded quadrilateral element based on field consistency approach is used for this study. The crack is modelled independent of the underlying mesh using partition of unity method (PUM), the extended finite element method (XFEM). The material properties are assumed to be graded only in the thickness direction and the effective material properties are estimated using the rule of mixtures. The plate kinematics is described based on the first order shear deformation theory (FSDT) and the shear correction factors are evaluated employing the energy equivalence principle. The influence of the crack length, the crack orientation, the flow angle and the gradient index on the aerodynamic pressure and the frequency are numerically studied. The results obtained here reveal that the critical frequency and pressure decrease with increase in crack the length and are minimum when the crack is aligned to the flow angle.

Introduction

The emergence of functionally graded materials (FGMs) that combine the best properties of its constituent materials (for example, ceramics and metals) is considered to be an alternative to certain class of aerospace structures exposed to high temperature environment. FGMs are characterized with a smooth transition from one material to another, thus circumventing high inter-laminar shear stresses and delamination problem that persists in laminated composites. With the increased use of these materials, it necessitates to study the dynamic characteristics of the structures made up of FGMS.

Background

It can be seen from the literature that the introduction of FGMs has attracted researchers to investigate the structural behaviour of such structures. Analytical solutions are proposed based on the three-dimensional solutions and second-order shear deformation theory. Different plate theories, viz., FSDT, second and other higher order accurate theory have been used to describe the plate kinematics. The static and dynamic fracture mechanics study of FGMs have been studied in the literature. Dolbow and Gosz employed the XFEM to compute mixed mode stress intensity factors. However, such analysis of plates is scarce in the literature. Huang et al., have analysed the vibration of side-cracked FGM thick plate analytically by employing Ritz procedure, whereas, Natarajan et al., examined the FGM plate with through center crack using the XFEM. Chau-Dinh et al., and Rabczuk et al., employed phantom node methods and meshfree methods with external enrichment to study the response of shells with arbitrary cracks.

Since FGMs are seen as potential candidates for aircraft structural applications, it is important to understand the dynamic characteristics of structures made up of such materials when exposed to air flow. Prakash and Ganapathi studied the linear flutter characteristics of FGM panels exposed to supersonic flow. Haddadpour et al., and Sohn and Kim investigated the nonlinear aspects of flutter characteristics using the finite element method. It can be seen from the available literature that the work on flutter characteristics of FGM plates with cracks, to the author’s knowledge is not available. Earlier studies on flutter characteristics of cracked isotropic and composite panels employed finite element procedure. Although these numerical studies give insight into the
understanding of flutter behaviour, the method requires the mesh to conform to the geometry. This inherently limits the analyses to fixed calculation parameters.

**Approach**

In this paper, we apply the XFEM to model the crack independent of the underlying mesh and then to study the flutter behaviour of FGM plates immersed in a supersonic flow based on the FSDT. Here, an enriched four nodded Co shear flexible quadrilateral plate element based on the consistency approach is used to analyse the flutter behaviour. To the author’s knowledge the flutter characteristics of FGM plates with arbitrary cracks has not been studied earlier. The influence of the crack length, the crack orientation, the flow direction and the material property on the evaluation of critical speed and the type of fluttering instability is numerically studied.

**Outline**

The paper is organized as follows, the next section will give an introduction to FGM and a brief overview of Reissner-Mindlin plate theory. The spatial discretization and the basic idea of the XFEM are presented in Section 3. Section 4 presents results for the flutter analyses of cracked functionally graded material panels, followed by concluding remarks in the last section.

**Formulation**

**Functionally Graded Material**

A rectangular plate made up of a mixture of ceramic and metal is considered with the coordinates x,y along the in-plane directions and z along the thickness direction (see Figure 1). The material on the top surface (z = h/2) of the plate is ceramic and graded to metal at the bottom surface (z=-h/2) by a power law distribution. The effective Young’s modulus E and Poisson’s ratio γ of the FGM, evaluated using the rule of mixtures as:

\[ E = E_c V_c + E_m V_m \]
\[ \gamma = \gamma_c V_c + \gamma_m V_m \]

where \( V_i (i=c,m) \) is the volume fraction of the material. The subscripts c and m refer to ceramic and metal phases respectively. The volume fraction of the ceramic and metal phases are related by

\[ V_c + V_m = 1 \]

and \( V_c = \frac{k(2z+h)}{2h} \), where \( k \) is the volume fraction exponent \((k > 0)\), also called the gradient index.

**Reissner-Mindlin Plate Theory**

Using Mindlin formulation, the displacements \((u,v,w)\) at a point \((x,y,z)\) in the plate from the medium surface are expressed as functions of midplane displacements \((u_0,v_0,w_0)\) and independent rotations \(\beta_x\) and \(\beta_y\) of the normal in \(xz\) and \(yz\) planes, respectively as:

\[
\begin{align*}
    u(x, y, z, t) &= u_0(x, y, t) + z\beta_x(x, y, t) \\
    v(x, y, z, t) &= v_0(x, y, t) + z\beta_y(x, y, t) \\
    w(x, y, z, t) &= w_0(x, y, t)
\end{align*}
\]

(1)

The midplane membrane strains \(\varepsilon_p\), the bending strains \(\varepsilon_b\) and the shear strain \(\varepsilon_s\) are written as

\[
\begin{align*}
    \varepsilon_p &= \begin{bmatrix} u_{0,x} \\ v_{0,y} \\ u_{0,y} + v_{0,x} \end{bmatrix} ,
    \varepsilon_b &= \begin{bmatrix} \beta_x \\ \beta_y \\ \beta_x + \beta_y \end{bmatrix} ,
    \varepsilon_s &= \begin{bmatrix} \beta_x + w_{0,x} \\ \beta_y + w_{0,y} \end{bmatrix} .
\end{align*}
\]

(2)

where the subscript ‘comma’ represents the partial derivative with respect to the spatial coordinate succeeding it. The strain energy of the plate can be expressed in terms of the field variables \(\delta = (u_0,v_0,w_0,\beta_x,\beta_y)\) and their derivatives as:

\[
U(\delta) = \frac{1}{2} \int_\Omega \left\{ \varepsilon_p^T A \varepsilon_p + \varepsilon_b^T B \varepsilon_b + \varepsilon_s^T D \varepsilon_s + \varepsilon_s^T E \varepsilon_s \right\} \right d\Omega
\]

(3)

where the matrices \(A,B,D,E\) are the extensional, bending-extensional coupling, bending and transverse shear stiffness coefficients. The kinetic energy of the plate is given by:
where \( \rho(z) \) is the mass density that varies through the thickness of the plate. The work done by the applied non-conservative load is:

\[
W(\delta) = \int_{\Omega} \Delta p w \, d\Omega
\]

where \( \Delta p \) is the aerodynamic pressure. The aerodynamic pressure based on first order, high Mach number approximation to linear potential flow is given by:

\[
\Delta p = -\frac{\rho a^2 U_a^2}{\sqrt{M_\infty^2 - 1}} (w_x \cos \theta' + w_y \sin \theta' + \chi w_z)
\]

where \( \chi = \left( \frac{1}{M_\infty^2 - 1} \right)^{\frac{1}{2}} \), \( \rho_a \), \( U_a \), \( M_\infty \), and \( \theta' \) are the free stream air density, velocity of the air, Mach number and the flow angle, respectively. The static aerodynamic approximation for Mach numbers between \( \sqrt{2} \) and 2 is obtained by setting \( \chi = 0 \) in Equation (6). The governing equations obtained using the minimization of total potential energy are solved based on the finite element method. The finite element equations thus derived are:

\[
[(K + \lambda A) - \omega^2 M] \delta = 0
\]

where \( K \) is the stiffness matrix, \( M \) is the consistent mass matrix, \( \lambda = -\frac{\rho a U_a^2}{\sqrt{M_\infty^2 - 1}} \), \( A \) is the aerodynamic force matrix and \( \omega \) is the natural frequency. When \( \lambda = 0 \), the eigenvalue of \( \omega \) is real and positive, since the stiffness matrix and the mass matrix are symmetric and positive definite. However, the aerodynamic matrix \( A \) is unsymmetric and hence complex eigenvalues \( \omega \) are expected for \( \lambda > 0 \). As \( \lambda \) increases monotonically from zero, two of these eigenvalues will approach each other and become complex conjugates. In this study, \( \lambda_0 \) is considered to be the value of \( \lambda \) at which the first coalescence occurs.

### Spatial Discretization

The plate element employed here is a \( C^0 \) continuous shear flexible field consistent element with 5 degrees of freedom \((u_o, v_o, w_o, \beta_x, \beta_y)\) at four nodes in a 4-noded bilinear quadrilateral (QUAD-4) element. The shear locking behaviour is suppressed by using the field redistributed substitute shape functions to interpolate the shear strains. The conventional polynomial expansion of the displacement field fails to capture the local behaviour of the problem. The basic idea in the XFEM is to append the conventional expansion of the displacement field with additional functions. The additional functions, also called the ‘enrichment functions’ carry additional information regarding the local behaviour. In general, the field variables are approximated by:

\[
u^h(x) = \sum_{I \in \mathcal{N}^{elem}} N_I(x) q_I + \text{enrichment functions}
\]

where \( N_I(x) \) are the standard finite element shape functions and \( q_I \) are the nodal variables associated with node \( I \). The following enriched approximation proposed by Dolbow et al., for the plate displacements are used:

\[
(u^h, v^h, w^h) (x) = \sum_{I \in \mathcal{N}^{elem}} N_I(x) (u^h_I, v^h_I, w^h_I) + \sum_{J \in \mathcal{N}^\infty} N_J(x) H(x) (b^h_J, b^h_{Jy}, b^h_{Jy}) + \sum_{K \in \mathcal{N}_e} N_K(x) \left( \sum_{l=1}^4 (c^h_{K1}, c^h_{K2}, c^h_{K3}) G_l(r, \theta) \right)
\]

The section rotations are approximated by:

\[
\beta^h_x(x) = \sum_{I \in \mathcal{N}^{elem}} \tilde{N}_{11}(x) \beta^h_{x I} + \sum_{J \in \mathcal{N}^\infty} \tilde{N}_{1J}(x) H(x) \beta^h_{xj} + \sum_{K \in \mathcal{N}_e} \tilde{N}_{1K}(x) \left( \sum_{l=1}^4 c^h_{Kl} F_l(r, \theta) \right)
\]

\[
\beta^h_y(x) = \sum_{I \in \mathcal{N}^{elem}} \tilde{N}_{21}(x) \beta^h_{y I} + \sum_{J \in \mathcal{N}^\infty} \tilde{N}_{2J}(x) H(x) \beta^h_{yJ} + \sum_{K \in \mathcal{N}_e} \tilde{N}_{2K}(x) \left( \sum_{l=1}^4 c^h_{Kl} F_l(r, \theta) \right)
\]

where \( \mathcal{N}^{elem} \) is a set of all nodes in the finite element mesh, \( \mathcal{N}_e \) is a set of nodes that are enriched with the Heaviside function, \( H(x) \) and \( \mathcal{N}^\infty \) are a set of nodes that are enriched with near tip asymptotic fields, \( G_l(r, \theta) \) and \( F_l(r, \theta) \). In Equations (9) and (10), \((u^h_I, v^h_I, w^h_I, \beta^h_{xI}, \beta^h_{yI})\) are the nodal unknown vectors associated with the continuous part of the finite
element solution, $b_J$ is the nodal enriched degree of freedom vector associated with the Heaviside (discontinuous) function and $c_K$ is the nodal enriched degree of freedom vector associated with the elastic asymptotic near-tip functions.

A special care must be taken to numerically integrate the stiffness matrix due to the addition of non-polynomial functions. The standard Gauss quadrature cannot be applied to elements enriched by discontinuous terms, because Gauss quadrature implicitly assumes a polynomial approximation. In the present study, a triangular quadrature with subdivision aligned to the discontinuity surface is employed. For the elements that are not enriched, a standard 2x2 Gaussian quadrature rule is used. The other techniques that can be employed are Schwarz Christoffel Mapping, Generalized quadrature and the Smoothed eXtended FEM.

Results and Discussion

In this section, we present the critical aerodynamic pressure and the critical frequency of a cracked simply supported FGM panels using the extended Q4 formulation. The element has five nodal degrees of freedom $(u_0, v_0, w_0, \beta_x, \beta_y)$. A full integration scheme is applied to evaluate the various strain energy terms. A simply supported boundary condition is assumed for the current study given by: $u_0 = v_0 = \beta_y = 0$ on $x = 0, a$; $v_0 = w_0 = \beta_x = 0$ on $y = 0, b$. In all cases, we present the non-dimensionalized critical aerodynamic pressure $\lambda_{cr}$ and critical frequency $\omega_{cr}$ as

$$\omega_{cr} = \frac{\Omega_{cr} a^2}{p_b h D_c}, \lambda_{cr} = \frac{\lambda_{cr} a^3}{D_c},$$

unless specified otherwise, where $D_c = \frac{E_c h^3}{12(1-\nu^2)}$ is the bending rigidity of the plate. The subscript $c$ refers to the material property corresponding to the ceramic phase. For this study, the plate thickness is assumed to be $a/h=100$. The effect of material property, the crack orientation $\theta$, the crack length $d/a$ and the flow angle $\theta'$ on the flutter behaviour are studied numerically. Based on a progressive mesh refinement, a 34x34 structured quadrilateral mesh is found to be adequate to model the full plate for the present analysis. The FGM plate considered here consists of silicon nitride (Si$_3$N$_4$) and stainless steel (SUS304). The Young’s modulus and the mass density for Si$_3$N$_4$ are $E_c = 348$ GPa, $\rho_c = 2370$ Kg/m$^3$ and for SUS304 are $E_m = 201.04$ GPa and $\rho_m = 8166$ Kg/m$^3$. Poisson’s ratio $\gamma$ is assumed to be constant and taken as 0.3.

Before proceeding with the detailed study, the formulation developed herein is validated against available results pertaining to the critical aerodynamic pressure and the critical frequency for an isotropic plate without a crack. The computed critical aerodynamic pressure and the critical frequency for an isotropic square plate with various boundary conditions are given in Table 1. It can be seen that the results from the present formulation are in good agreement with those in the literature.

![FIG. 2 SIMPLY SUPPORTED PLATE WITH A CENTER CRACK](image)

Next, the flutter characteristics of square simply supported cracked FGM plates is investigated. Consider a plate of uniform thickness, $h$ and with length and width as $a$ and $b$, respectively. Figure 2 shows a plate with all edges simply supported with a center crack of length $d$ and a distance of $c_y$ from the x-axis. In this example, the influence of the crack length $d/a$, the crack orientation $\theta$, the flow angle $\theta'$ and the gradient index $k$ on the critical aerodynamic pressure and the critical frequency is studied. Figure 3 shows the variation of the critical aerodynamic pressure $\lambda_{cr}$ and the critical frequency $\omega_{cr}$ with gradient index $k$ on the critical aerodynamic pressure and the critical frequency is studied. Figure 3 shows the variation of the critical aerodynamic pressure $\lambda_{cr}$ and the critical frequency $\omega_{cr}$ with gradient index $k$ on the critical aerodynamic pressure and the critical frequency is studied. This is because of the stiffness degradation due to increase in the

TABLE 1 COMPARISON OF CRITICAL AERODYNAMIC PRESSURE AND COALESCENCE FREQUENCY FOR AN ISOTROPIC PLATE WITH VARIOUS BOUNDARY CONDITIONS (SSSS – ALL EDGES SIMPLY SUPPORTED, CCC – ALL EDGES CLAMPED) AND \((A/B = 1, A/H = 100, \gamma = 0.3, \theta' = 0\))
metallic volume fraction. Figure 4 shows the influence of the crack length \( d/a \) on the critical aerodynamic pressure and the critical frequency. It is observed that as the crack length increases, the critical aerodynamic pressure and the critical frequency decreases. This is due to the fact that increasing the crack length increases the local flexibility and thus decreases the frequency. It can be seen that the combined effect of increasing the crack length and the gradient index is to lower the critical frequency and the critical pressure. It can also be observed from Figure 3 that the critical pressure and the frequency drop sharply for slight increase in the metallic volume fraction, but with further increase in the metallic volume fraction, the drop in the pressure and the frequency is marginal. In both cases, the decrease in the critical aerodynamic pressure and the critical frequency is due to the stiffness degradation.

Figure 5 shows the influence of the crack angle \( \theta \) on the critical pressure and the frequency for a simply supported square FGM plate with \( d/a = 0.5 \), immersed in a normal flow \( \theta' = 0^\circ \). From Figure 5, it can be seen that with increase in the crack orientation, the critical pressure increases gradually until the crack is oriented at right angles to the flow angle and with further increase in the crack orientation, the critical pressure and the frequency decreases. Further, it is observed that the critical pressure is the lowest for a crack orientation \( \theta = 0^\circ \) and \( 180^\circ \). At these crack orientations, the crack is aligned to the flow direction. The critical frequency and the pressure values tend to be symmetric with respect to a crack orientation \( \theta = 90^\circ \).

Figure 6 shows the effect of flow angle \( \theta' \) on the critical aerodynamic pressure for a simply supported square FGM plate with a center horizontal crack \( d/a = 0.5 \) and gradient index \( k = 5 \).
The influence of the flow angle on the critical pressure for a simply supported square FGM plate with gradient index $k = 5$ is shown in Figure 6 for different crack orientations, i.e., $\theta = -45^\circ, 0^\circ$ and $+45^\circ$. It is observed that the critical pressure is minimum when the crack is aligned to the flow angle. The critical frequency increases for other flow angles irrespective of the orientation of the crack.

**Conclusions**

The flutter characteristics of cracked FGM panels immersed in a supersonic flow has been analysed based on the first order shear deformation theory within the framework of the extended finite element approach. The aerodynamic force is accounted for assuming the first-order Mach number approximation potential flow theory and the homogenized material properties are estimated by rule of mixtures. Numerical experiments have been conducted to bring out the effect of the gradient index, the crack length, the crack orientation and the flow angle on the flutter characteristics of the FGM panel. From the detailed numerical study, it can be concluded that with increasing gradient index and the crack length, the critical pressure and the critical frequency decreases. In both cases, the decrease is due to the stiffness degradation. It is also observed that the critical frequency and the pressure are minimum when the crack is aligned to the flow.
