Fluctuation Relations and Crystallization

Motivation

Hard Spheres undergo a fluid to solid phase transition if the packing fraction is approx. > 0.5. The nucleation process itself and structure formation in this transient process are still under investigation. Here a new approach is proposed to correlate forming structure and dissipation directly. Fluctuation relations are the method of choice. Increasing the pressure with time results in thermodynamic work, linked by the first law of thermodynamics to dissipation.

Studying fluctuation relations of structural phase transition and even slow dynamics is important. A new kind of fluctuation enters the dynamics that is macroscopic instead of microscopic based on thermal fluctuations.

Model

Monodisperse Hard Spheres are described by the volume fraction \( \phi \).

Important facts:

- Very high energy barrier at low over compression, i.e. very small nucleation rates.
- Latent heat at the phase transition is purely entropic because of hard potentials.
- Coexistence pressure \( P_{\text{coex}} \) = 11.45.
- Spinodal regime and even glassy dynamics at high packing fractions [1].

Illustration of the compression:

\[
P_{\text{coex}} \rightarrow P_{\text{f}} \rightarrow P_{0}
\]

Basic Concepts

The system is compressed by an external time dependent pressure, \( P_t \rightarrow P_r \).

Thermodynamic work (NPT ensemble):

\[
W = \int_0^\tau dt \dot{P} V(t)
\]

The Crooks relation [2]:

\[P_r W / P_0 (-W) = \exp(-\beta(W - \Delta G))\]

The Jarzynski relation [3]:

\[
\langle \exp(-\beta W) \rangle = \exp(-\beta \Delta G)
\]

Dissipation and Structure

Resulting transient structures on log scale. Structure is measured via \( |q_4| \) and \( |q_6| \) [4].

Particles are considered for: if \( |q_4| > 0.35 \) and \( |q_6| > 0.125 \).

and if \( |q_6| > 0.35 \) and \( |q_4| < 0.06 \).

Conclusion and Outlook

The crystallization process is characterised by a macroscopic fluctuation. Fluctuation theorems capture this effect. Dissipation can be calculated during this transient process and allows one to study correlations to the emerging structures. Work distributions are not Gaussian in this case. An additional Poisson process is present. This phenomena here studied for the most simple liquid, should be extended to dynamic arrest, anisotropy, and interactions exhibiting latent heat.
