Abstract—Despite the deleterious effect of hardware impairments on communication systems, most prior works have not investigated their impact on widely used relay systems. Most importantly, the application of inexpensive transceivers, being prone to hardware impairments, is the most cost-efficient way for the implementation of massive multiple-input multiple-output (MIMO) systems. Consequently, the direction of this paper is towards the investigation of the impact of hardware impairments on MIMO relay networks with large number of antennas. Specifically, we obtain the general expression for the ergodic capacity of dual-hop (DH) amplify-and-forward (AF) relay systems. Next, given the advantages of the free probability (FP) theory with comparison to other known techniques in the area of large random matrix theory, we pursue a large limit analysis in terms of number of antennas and users by shedding light to the behavior of relay systems inflicted by hardware impairments.

I. INTRODUCTION

Since the publication of the seminal papers of Telatar and Foschini [1], [2], showing the linear growth of the channel capacity by increasing the number of transmit and receive antennas, multiple-input multiple-output (MIMO) systems have attracted a tremendous interest. Especially, the demand for a thousand-fold higher capacity in 5G systems has brought to the forefront a promising technique with numerous advantages, known as massive MIMO, where the base station (BS) includes a very large number of antennas [3]. The research on massive MIMO has been approached mostly by applying tools from large random matrix theory such as the Silverstein’s fixed-point equation and the technique of deterministic equivalents [4]–[7]. However, most works in conventional and massive MIMO have been based on the strong assumption of using perfect hardware in the radio-frequency (RF) chains.

Indisputably, in practical systems, numerous detrimental effects such as I/Q imbalance [8] and high-power amplifier nonlinearities [9], appear and result to the degradation of the performance of MIMO systems. Despite the effort for mitigation of the arising impairments by application of calibration schemes at the transmitter and/or compensation algorithms at the receiver [10], residual distortions remain because of several reasons. For example, imperfect parameters estimation and inaccurate models prove to be incapable to hinder the total infliction of the system’s performance. Not to mention that the cost-efficiency of the suggested for 5G massive MIMO technology rests on the application of inexpensive hardware, which will make the deleterious effect of the residual impairments more pronounced.

Disregarding the importance for study of the effects of the residual transceiver impairments, the number of relevant works is limited. For instance, experimental results modeling the residual hardware impairments at the transmitter and the study of their impact on certain MIMO detectors such as zero-forcing took place in [11]. Regarding the channel capacity, [12] elaborated on the derivation of high signal-to-noise ratio (SNR) ceilings by considering only transmitter impairments, while in [13] the authors extended the analysis to arbitrary SNR values, but most importantly, by including receiver impairments as well. Moreover, the authors in [14] considered this kind of impairments in dual-hop (DH) amplify-and-forward (AF) relay systems, which have attracted a lot of attention recently due to their performance benefits in terms of coverage extension, spatial diversity gains, etc. [15]. Unlikely, they considered only the outage probability and some simple capacity upper bounds in the simplistic case of single antenna systems. However, a thorough analysis of the capacity of relay systems in the case of multiple antennas lacks from the literature.

This work covers the arising need for the assessment of the impact of the residual hardware impairments on the capacity of DH AF systems, when their size becomes large in terms of number of antennas and users. In fact, to the best of our knowledge, this is the first paper which studies the effect of residual impairments in relay systems with multiple antennas. Specifically, we present a new insightful expression for the ergodic capacity of DH AF systems under the presence of residual hardware impairments for arbitrary SNR values. Compared to the existing literature, we pursue a free probability (FP) analysis [4], [16], which requires just a polynomial solution instead of fixed-point equations, and provide a thorough characterization of the impact of the residual transceiver impairments on the capacity of DH AF systems in the large system limit.

The remainder of this paper is organized as follows: Section II presents the system model of a DH AF MIMO system with residual hardware impairments. Section III provides the theoretical analysis for the ergodic capacity of the considered system, while Section IV presents asymptotic capacity expressions. Subsequently, Section V evaluates the performance of the considered system with the help of numerical results. Finally, Section VI concludes the paper. Appendices include some preliminaries on random matrix theory and certain proofs.

II. SYSTEM MODEL

Suppose an ideal DH AF relay channel with $K$ single antenna non-cooperative users, desiring to communicate with
a distant $N$-antennas BS by first contacting an intermediate relay including an array of $M$ antennas (first hop). In other words, a single-input multiple-output multiple access channel (SIMO MAC), i.e., users-relay, is followed by a point to point MIMO channel (relay-BS). The BS is assumed to be aware of the total system channel state information (CSI) and the statistics of the distortion noises, while both the users and the relay have no CSI knowledge during their transmission. The received signals by the relay and the BS are expressed as

\[ y_1 = H_1 x_1 + z_1, \]
\[ y_2 = H_2 \sqrt{\nu} y_1 + z_2 = \sqrt{\nu} H_2 H_1 x_1 + \sqrt{\nu} H_2 z_1 + z_2, \]

where (1) and (2) describe the users-relay and relay-BS input-output signal models, respectively. Specifically, $y_1$ and $y_2$ as well as $z_1 \sim \mathcal{CN}(0, I_M)$ and $z_2 \sim \mathcal{CN}(0, I_N)$ denote the received signals as well as the additive white Gaussian noise (AWGN) vectors at the relay and BS, respectively. Both channels representing the two hops assume Rayleigh fast-fading channels, expressed by Gaussian matrices with independent and identically distributed (i.i.d.) complex circular symmetric elements. Hence, $H_1 \in \mathbb{C}^{M \times K}$, $H_2 \in \mathbb{C}^{N \times M}$, and $H_1 x_1 + z_1$ describes the channel matrix of the second hop. In this case, $x_1 \in \mathbb{C}^{K \times 1}$ is the Gaussian vector of symbols simultaneously transmitted by the BS users with $E[x_1 x_1^\dagger] = Q_1 = \frac{\mu}{K} I_K$, i.e., the individual signal-to-noise-ratio (SNR) equals to $\mu = \frac{\nu}{\rho}$. Note that before forwarding the received signal $y_1$, at the relay, we have assumed that it is amplified by $\nu = \frac{\alpha}{\sqrt{M(1+\rho)}}$, where we have placed a per relay-antenna fixed power constraint $\frac{\alpha}{M}$, i.e., $E[\|\sqrt{\nu} y_1\|^2] \leq \alpha$, where the expectation is taken over all random variables.

Unfortunately, in practice, the transmitter, the relay, and the BS appear certain inevitable impairments such as I/Q imbalance [10]. Although, mitigation schemes are incorporated in both the transmitter and the receiver, residual impairments still emerge by means of additive distortion noises [10]. Taking this into consideration, in each part of the system a transmit and/or receive impairment exists that causes: 1) a mismatch between the intended signal and what is actually transmitted during the transmit processing, 2) and/or a distortion of the received signal at the receiver side.

Introduction of the residual additive transceiver impairments to (1) and (2) provides the more general channel models for the respective links

\[ y_1 = H_1 (x_1 + \eta_1) + \eta_{\pi_1} + z_1, \]
\[ y_2 = H_2 (\sqrt{\nu} y_1 + \eta_2) + \eta_{\pi_2} + z_2 = \sqrt{\nu} H_2 H_1 (x_1 + \eta_1) + \eta_{\pi_2} + \eta_{\pi_1} + z_2, \]

where the additive terms $\eta_{\pi_i}$ and $\eta_{\pi_1}$ for $i = 1,2$ are the distortion noises coming from the residual impairments in the transmitter and receiver of link $i$, respectively. Interestingly, this model allows to quantify the impact of the additive residual transceiver impairments, described in [10], [11], on a DH AF system. Generally, the transmitter and the receiver distortion noises for the $i$th link are modeled as Gaussian distributed, where their average power is proportional to the average signal power, as shown by measurement results [11]. Mathematically speaking, we have

\[ \eta_{\pi_1} \sim \mathcal{CN}(0, \delta_{\pi_1}^2 \text{diag}(q_1, \ldots, q_T)), \]
\[ \eta_{\pi_2} \sim \mathcal{CN}(0, \delta_{\pi_2}^2 \text{tr}(Q_i) I_K), \]

with $T_i$ and $R_i$ being the numbers of transmit and receive antennas of link $i$, i.e., $T_1 = K$, $T_2 = M$ and $R_1 = M$, $R_2 = N$, while $Q_i$ is the transmit covariance matrix of the corresponding link with diagonal elements $q_1, \ldots, q_T$. Moreover, $\delta_{\pi_1}^2$ and $\delta_{\pi_2}^2$ are proportionality parameters describing the severity of the residual impairments in the transmitter and the receiver of link $i$. Especially, in practical applications, these parameters appear as the error vector magnitudes (EVM) at each transceiver side [17]. Obviously, as far as the first hop is concerned, the additive transceiver impairments are expressed as

\[ \eta_{\pi_1} \sim \mathcal{CN}(0, \delta_{\pi_1}^2 \rho I_K), \]
\[ \eta_{\pi_2} \sim \mathcal{CN}(0, \delta_{\pi_2}^2 I_M), \]

Given that the input signal for the second hop is $\sqrt{\nu} y_1$, the corresponding input covariance matrix is

\[ Q_2 = \nu E[y_1 y_1^\dagger] = \nu K \left( I + \delta_{\pi_2}^2, \mu + \delta_{\pi_1}^2, \mu + \frac{1}{K} \right) I_M = \nu K I_M, \]

where $\tilde{\eta} = (\mu + \delta_{\pi_1}^2, \mu + \delta_{\pi_2}^2, \mu + \frac{1}{K})$. Note that now, $\nu = \frac{\alpha}{\sqrt{M\rho}}$, after accounting for fixed gain relaying. Thus, the additive transceiver impairments for the second hop take the form

\[ \eta_{\pi_2} \sim \mathcal{CN}(0, \delta_{\pi_2}^2 \tilde{\eta} K I_M), \]
\[ \eta_{\pi_3} \sim \mathcal{CN}(0, \delta_{\pi_3}^2 \tilde{\eta} M I_N). \]

III. Ergodic Capacity Analysis

The capacity per receive antenna of this channel model is given by the following lemma, which takes (4) into account.

**Lemma 1:** The capacity per receive antenna of a DH AF system in the presence of i.i.d. Rayleigh fading with residual additive transceiver hardware impairments under per user power constraints $[Q_i]_{k,k} \leq \mu, \forall k = 1 \ldots K$ and (9) is given by

\[ C = \frac{1}{N} \mathbb{E} \left[ \ln \text{det} \left( I_N + \frac{\mu \nu}{B} H_2 H_1 H_1^H H_2^H \Phi^{-1} \right) \right] \]
\[ = \frac{1}{N} \mathbb{E} \left[ \ln \text{det} \left( \Phi + \frac{\mu \nu}{B} H_2 H_1 H_1^H H_2^H \right) \right] \]
\[ - \frac{1}{N} \mathbb{E} \left[ \ln \text{det} (\Phi) \right], \]

where $\Phi = f_2 H_2 H_1 H_1^H H_2^H + f_3 H_2 H_2^H + I_N$ with $B = \rho + \mu K M + 1$, $f_1 = \frac{\nu}{\sqrt{f_2}}$, $f_2 = f_4 \delta_{\pi_2}^2$, $f_3 = \nu (\delta_{\pi_1}^2, \mu K + \delta_{\pi_2}^2, \mu K + 1)$, and $f_4 = \frac{\mu \nu}{B}$.

**Proof:** Given any channel realizations $H_1, H_2$ and transmit signal covariance matrices $Q_i$ and $Q_2$ at the user and relay sides, a close observation of (4) shows that it is an instance of
the standard DH AF system model described by (2), but with a
different noise covariance given by
\[
\Phi = \nu \delta_1^2 \mathbf{H}_2 \mathbf{H}_1^\dagger \text{diag} (q_1, \ldots, q_K) \mathbf{H}_2^\dagger \mathbf{H}_2^\dagger \\
+ \mathbf{H}_2 \left( (\nu \delta_1^2 \nu \mathbf{Q}_1 + \nu) \mathbf{I}_N + \nu \delta_2^2 \text{diag} (q_1, \ldots, q_M) \right) \mathbf{H}_2^\dagger \\
+ (\delta_2^2 \nu \mathbf{Q}_2 + 1) \mathbf{I}_N. \tag{14}
\]
Taking into account for the optimality of the input signal
\( \mathbf{x}_1 \) because it is Gaussian distributed with covariance matrix
\( \mathbf{Q}_1 = \frac{\mu}{\nu} \mathbf{I}_K \), the proof is concluded.

Based on Lemma 1, we are able to investigate the impact
of the additive transceiver impairments on DH AF systems in
the case of infinitely large system dimensions.

Remark 1: Despite the resemblance of the ergodic capacity
with transceiver impairments, given by (12), with the convention-
"nal ergodic capacity of a DH AF system [18, Eq. 2], this
paper shows the fundamental differences that arise because the
noise covariance matrix now depends on the combination of
the channel matrices \( \mathbf{H}_1, \mathbf{H}_2 \).

Employing the property \( \det (\mathbf{I} + \mathbf{AB}) = \det (\mathbf{I} + \mathbf{BA}) \), \( C_1, C_2 \)
can be alternatively written as
\[
C_1 = \frac{1}{N} \mathbb{E} \left[ \ln \det \left( \mathbf{I}_M + f_\beta \mathbf{H}_2^\dagger \mathbf{H}_2 \left( \mathbf{I}_M + f_\gamma \mathbf{H}_1 \mathbf{H}_1^\dagger \right) \right) \right] \tag{15}
\]
\[
C_2 = \frac{1}{N} \mathbb{E} \left[ \ln \det \left( \mathbf{I}_M + f_\beta \mathbf{H}_2^\dagger \mathbf{H}_2 \left( \mathbf{I}_M + f_\gamma \mathbf{H}_1 \mathbf{H}_1^\dagger \right) \right) \right]. \tag{16}
\]

IV. ASYMPTOTIC PERFORMANCE ANALYSIS

This section presents the main results regarding the system
performance in the large-antenna regime. Nevertheless, we
account also for the scenario, where the number of users
increases infinitely. Given that our interest is focused on
channel matrices with dimensions tending to infinity, we employ
tools from large RMT. Among the advantages of the ensuing
analysis, we mention the achievement of deterministic results
that make Monte Carlo simulations unnecessary. Moreover, the
asymptotic analysis can be quite accurate even for realistic
system dimensions, while its convergence is rather fast as the
channel matrices grow large. Thus, after defining \( \beta \triangleq \frac{\alpha}{M} \) and
\( \gamma \triangleq \frac{\alpha}{N} \), the channel capacity of the system under study is
given by the following theorem.

Theorem 1: The capacity of a DH AF MIMO system in the
presence of i.i.d. Rayleigh fading channels with additive
transceiver impairments, when the number of transmit users \( K \)
as well as relay and BS antennas \( (M \) and \( N \) tend to infinity
with a given ratio, is given by
\[
C \rightarrow \frac{1}{\gamma} \int_0^\infty \ln \left( 1 + f_\beta M x \right) \left( f_{\mathbf{K}_{1}/M}^\infty (x) - f_{\mathbf{K}_{1}/\gamma}^\infty (x) \right) dx, \tag{17}
\]
where the asymptotic eigenvalue probability density functions
(a.e.p.d.f.) \( f_{\mathbf{K}_{1}/M}^\infty \) and \( f_{\mathbf{K}_{1}/\gamma}^\infty \) are obtained by the imagi-
ary part of the corresponding Stieltjes transform \( S \) for real
arguments.

Proof: See Appendix B.

V. NUMERICAL RESULTS

In order to validate our theoretical analysis, Fig. 1 provides
the a.e.p.d.f. of \( \mathbf{K}_{\alpha}/M \) given by (30). In particular, the
histogram represents the p.d.f. of the matrix \( \mathbf{K}_{\alpha}/M \) calculated
numerically based on Monte Carlo (MC) simulations. Further,
the solid line denotes the a.e.p.d.f. obtained by solving the
polynomial (39) for Stieltjes transform, and then applying
Lemma 4. From the result, we can observe a perfect agreement
between the results obtained from theoretical analysis and MC
simulations.
In both cases, the capacity increases monotonically with both $\beta$ and $\frac{1}{\gamma}$; however, the slope with respect to $\frac{1}{\gamma}$ is steeper as compared to the slope with $\beta$. This trend remains almost the same in the presence of impairments, but the slope of the capacity curve with respect to $\frac{1}{\gamma}$ in Fig. 4(b) is observed to be less steeper than in Fig. 4(a) at higher values of $\frac{1}{\gamma}$.

VI. Conclusions

This paper presented a thorough investigation of the impact of residual additive hardware impairment on the ergodic capacity of DH AF MIMO relay channels by considering a large system analysis. Specifically, we derived the ergodic capacity by employing the theory of FP. Moreover, we proceeded with the study of the effects of hardware impairments, when the number of antennas becomes large as massive MIMO architecture demands. Notably, we demonstrated the quantification of the degradation due to the additive RF impairments on the ergodic capacity by varying the system parameters such as the SNR, the number of antennas, and the quality of the RF equipment. Nevertheless, the validation of the analytical results was shown by means of simulations. In particular, simulations depicted that the asymptotic results can be applicable even for contemporary system dimensions.

APPENDIX A

Useful Lemmas

Herein, given the eigenvalue probability distribution function $f_X(x)$ of a matrix $X$, we provide useful definitions and lemmas, found in [19], that are considered during our analysis. In the following definitions, $\delta$ is a nonnegative real number.

Definition 1 (Shannon transform [19, Definition 2.12]): The Shannon transform of a positive semidefinite matrix $X$ is
where their ratios $\beta$ and

$$\begin{align*}
\Sigma_X(x) &= -\frac{x+1}{x} \eta_\Sigma^{-1}(x+1).
\end{align*}$$

**Definition 3:** [S-transform [19, Definition 2.15]] The S-transform of a positive semidefinite matrix $X$ is defined as

$$\Sigma_X(x) = -\frac{x+1}{x} \eta_X^{-1}(x+1). \quad (20)$$

**Definition 4 (The Marchenko-Pastur law density function [20]):** Given a Gaussian $K \times M$ channel matrix $H \sim \mathcal{CN}(0, I)$, the a.e.p.d.f. of $\frac{1}{K} HH^H$ converges almost surely (a.s.) to the non-random limiting eigenvalue distribution of the Marchenko-Pastur law given by

$$f^\infty_{\frac{1}{K} HH^H}(x) = \left(1 - \beta^2\right)^+ x + \frac{\sqrt{(x-a)^+(b-x)^+}}{2\pi x}, \quad (21)$$

where $a = (1 - \sqrt{\beta})^2$, $b = (1 + \sqrt{\beta})^2$, $\beta = \frac{K}{M}$, and $\delta(x)$ is Dirac’s delta function.

**Lemma 2 ([19, Eqs. 2.87, 2.88]):** The S-transform of the matrix $\frac{1}{K}HH^H$ is expressed as

$$\Sigma_{\frac{1}{K}HH^H}(x, \beta) = \frac{1}{1 + \beta x}. \quad (22)$$

while the S-transform of the matrix $\frac{1}{K}HH^H$ is obtained as

$$\Sigma_{\frac{1}{K}HH^H}(x, \beta) = \frac{1}{1 + \beta x}. \quad (23)$$

**Lemma 3 ([19, Eq. 2.48]):** The Stieltjes-transform of a positive semidefinite matrix $X$ can be derived by its $\eta$-transform according to

$$S_X(x) = -\eta_X(-1/x). \quad (24)$$

**Lemma 4 ([19, Eq. 2.45]):** The a.e.p.d.f. of $X$ is obtained by the imaginary part of the Stieltjes transform $S$ for real arguments as

$$f^\infty_X(x) = \lim_{y \to 0^+} \frac{1}{\pi} \Im \{S_X(x + iy)\}. \quad (25)$$

**Appendix B**

**Proof of Theorem 1**

The asymptotic limits of the capacity terms (15) and (16), when the channel dimensions tend to infinity, while keeping their ratios $\beta$ and $\gamma$ fixed, are expressed by means of principles of FP theory in terms of a generic expression as

$$C_i = \frac{1}{N} \lim_{K,M,N \to \infty} \mathbb{E} \left[ \ln \det(I_M + f_3 H_2 H_2^T (I_M + \alpha H_1 H_1^H)) \right]$$

$$= \frac{M}{N} \lim_{K,M,N \to \infty} \left[ \frac{1}{M} \sum_{i=1}^{M} \ln \left(1 + f_3 M \lambda_i \left(\frac{1}{K} K_i\right)\right) \right]$$

$$\to \frac{1}{\gamma} \int_0^\infty \ln(1 + f_3 M x) f^\infty_{\frac{1}{K} HH^H}(x) \, dx, \quad (26)$$

where $C_i$ corresponds to $C_1$ or $C_2$ depending on the value of $i$, i.e., if $\alpha = f_1$ or if $\alpha = f_2 / f_3$, respectively. In addition, $\lambda_i(X)$ is the $i$th ordered eigenvalue of matrix $X$, and $f^\infty_X$ denotes the asymptotic eigenvalue probability density function (a.e.p.d.f.) of $X$. Moreover, for the sake of simplification of our analysis, we have made use of the following variable definitions similar to [21]

$$M_\alpha = I_M + \alpha H_1 H_1^H$$

$$N_1 = H_1 H_1^H$$

$$N_2 = H_2 H_2^H$$

$$K_\alpha = H_2^T H_2 (I_M + \alpha H_1 H_1^H) = N_2 M_\alpha. \quad (30)$$

The a.e.p.d.f. of $K_\alpha / M$ can be obtained by means of Lemma 4, which demands its Stieltjes transform. In the following, we describe the steps leading to the derivation of the desired Stieltjes transform of $K_\alpha / M$. First, we employ Lemma 3, and take the inverse of $\eta$-transform of $K_\alpha / M$ as

$$x \eta^{-1}_{K_\alpha / M}(x) = 1 = 0 \quad \quad (31)$$

Thus, we now focus on the derivation of $\eta^{-1}_{K_\alpha / M}(x)$.

**Proposition 1:** The inverse $\eta$-transform of $K_\alpha / M$ is given by

$$\eta^{-1}_{K_\alpha / M}(x) = \frac{1}{x} \eta^{-1}_{N_2 / M}(x - 1) \eta^{-1}_{\alpha M_\alpha / M}(x). \quad (32)$$

**Proof:** The inverse of the $\eta$-transform of $K_\alpha / M$ is given by means of the free convolution

$$S_{K_\alpha / M}(x) = S_{N_2 / M}(x) S_{\alpha M_\alpha / M}(x) \iff \left( \frac{x+1}{x} \right) \eta^{-1}_{K_\alpha / M}(x+1) = S_{N_2 / M}(x) \left( \frac{x+1}{x} \right) \eta^{-1}_{\alpha M_\alpha / M}(x+1), \quad (33)$$

where we have taken into account the asymptotic freeness between the determinisitic matrix with bounded eigenvalues $N_2 / M$ and the unitarily invariant matrix $M_\alpha / M$. Note that in (33), we have applied Definition 3. Appropriate change of variables, i.e., $y = x + 1$ provides eq. (32).

In order to obtain $\eta^{-1}_{K_\alpha / M}(x)$, we first need its a.e.p.d.f., given by the next proposition.

**Proposition 2:** The a.e.p.d.f. of $M_\alpha / M$ converges almost surely to (34) with $\alpha = M_\alpha$.

**Proof:** By denoting $z$ and $x$ the eigenvalues of $M_\alpha / M$ and $\frac{1}{\alpha} N_1$, respectively, the a.e.p.d.f. of $M_\alpha / M$ can be obtained after making the transformation $z(x) = (1 + M_\alpha x)$ as

$$f^\infty_{M_\alpha / M}(z) = \left| \frac{1}{z/(z-1)} \right| f^\infty_{\frac{1}{\alpha} N_1}\left(\frac{z-1}{\alpha}\right)$$

$$= \frac{1}{\alpha} f^\infty_{\frac{1}{\alpha} N_1}\left(\frac{z-1}{\alpha}\right). \quad (35)$$

Consequently, we are ready to obtain $\eta^{-1}_{M_\alpha / M}(x)$ by using (19).

**Proposition 3:** The inverse $\eta$-transform of $M_\alpha / M$ is given by (37).

**Proof**: Having obtained the a.e.p.d.f. of $M_\alpha$, use of Definition 2 allows to derive its $\eta$-transform as

$$\eta_{M_\alpha / M}(\psi) = \int_0^\infty \frac{1}{1 + \psi x} f^\infty_{M_\alpha / M}(x) \, dx.$$
If we make the necessary substitution, \( \eta_{M_\alpha/M}(\psi) \) is written as in (36). Following a similar procedure as in [22], we perform certain substitutions. Specifically, we set \( w = \sqrt{\beta} \cos \omega \), \( dw = 2 \sqrt{\beta} (-\sin \omega) d\omega \), and finally \( \zeta = e^{i\psi} \), \( d\zeta = i e^{i\psi} d\omega \). Hence, initially we calculate the poles \( \zeta_i \) and residues \( \rho_i \) of Eq. (36). Then, we perform an appropriate Cauchy integration by including the residues located within the unit disk. More concretely, we have

\[
\eta_{M_\alpha/M}(\psi) = -\frac{\beta}{2} (\rho_0 + \rho_2 + \rho_4),
\]

which after inversion results to Eq. (37).

As far as \( \Sigma_{N_2/M}(x) \) is concerned, it is given by (23) as

\[
\Sigma_{N_2/M}(x) = \frac{1}{\gamma + x}. \tag{38}
\]

In the last step, having calculated \( \eta_{K_\alpha/M}^{-1}(x) \) from (32) after substituting (37) and (38), we employ (31), and after tedious algebraic manipulations we obtain the following quartic polynomial

\[
\begin{align*}
\alpha^2 x^2 S_{K_\alpha/M}^4 + & (2\alpha^2 (1 - \gamma) x + \alpha^2 x^2) S_{K_\alpha/M}^3 \\
& + (2\alpha^2 (2 - \beta - \gamma) x + \alpha^2 (\gamma - 1) - \alpha x) S_{K_\alpha/M}^2 \\
& + (\alpha^2 (\beta (\gamma - 1) + \gamma + \alpha - x - 1)) S_{K_\alpha/M} - \alpha. \tag{39}
\end{align*}
\]
