CHARACTERIZATION OF NOVEL COVALENT AND
NON-COVALENT DRUGS AGAINST K-RAS
SURROGATE TARGETS

OKUTACHI Ojochegbe Sunday

A thesis submitted in partial fulfilment of the
Requirements for the degree of

Doctor of Philosophy in Biology

At the
University of Luxembourg

June 2021

This Doctoral Thesis was performed at the Department of Life Sciences and Medicine at the University of Luxembourg, under the supervision of Prof. Dr. Daniel Abankwa, principal investigator of the Cancer Cell Biology and Drug Discovery Laboratory. The PhD is funded by the University of Luxembourg under the starting grant of Prof. Abankwa's position.

Thesis supervisory committee:

Prof. Dr. Daniel Abankwa

University of Luxembourg, Luxembourg

Prof. Dr. Iris Behrmann

University of Luxembourg, Luxembourg

Prof. Dr. Krishnaraj Rajalingam

University Medical Center, Mainz, Germany

DLSM

DEPARTMENT OF LIFE SCIENCES
AND MEDICINE

Affidavit

Declaration of Authorship

I hereby confirm that the PhD thesis entitled “characterization of novel covalent and non-covalent drugs against K-Ras surrogate targets” is written independently and without any other external sources other than those cited.

Esch-sur-Alzette, May 03, 2021

OKUTACHI Ojochegbe Sunday

In all your ways acknowledge Him and He shall direct your paths

Proverbs 3:6

The past 3 years have been filled with so many lessons, opportunities and memories that would not have been possible without the help of several individuals from my professional and personal life.

Firstly, I wish to express my deepest gratitude to **Prof. Dr. Daniel ABANKWA**, my thesis supervisor and academic mentor for allowing me to work on this complex and stimulating topic of Ras biology. I will be forever grateful to you for taking a chance on me and welcoming me into your lab. Your academic mentorship and support has ensured that I grew rapidly as a scientist and helped me use my time optimally as demonstrated by this record time to graduation. I appreciate your patience and willingness to go the extra mile to impart knowledge. I appreciate your commitment to excellence and quality work, your frank comments and desire to bring out the best from your graduate students. My experience with you will remain a watershed moment in my life's story.

Also, I will like to specially thank the external jury members of my thesis defense committee **Prof. Ian PRIOR** of the University of Liverpool and **Prof. Chris MARSHALL** of University of Toronto for accepting to examine my thesis. Having read many of your seminal publications in Ras biology, I am honored to have such leading figures evaluate my work. My sincere gratitude goes to my thesis advisory committee members **Prof. Dr. Iris BEHRMANN** and **Prof. Dr. Khrishnaraj RAJALINGAM** for taking out time from your busy schedules to support the progress of my PhD training.

Furthermore, I will like to thank all the members of the Cancer Cell Biology and Drug Discovery Group especially **Dr. Ganesh babu MANOHARAN**, **Dr. Elisabeth RECKINGER-SCHAFFNER**, **Marie CATILLON** and **Christina LAURINI** for all the help and support on the bench and off the bench. I am grateful to **Ganesh** who not only served as an unofficial supervisor but also a good friend and support in my darkest hours of need. You so generously offered scientific and personal

advice and helped ensure that I stayed grounded during this PhD. Your kindness is appreciated. Thank you **Lis** for the often resourceful ideas on experiments and assay optimization as well as your hospitality when we first arrived in Luxembourg and subsequently. Interacting with you is always a pleasure, your commitment to common decency and family values has no doubt rubbed off on me. You will be remembered fondly. Thank you **Marie**, our multi-talented research technologist who so gracefully taught me many useful techniques for my project. Your abilities on the bench are rare and so is your willingness to share knowledge. Thank you **Christina** for helping out with microscopy and making sure we did not run-out of critical items during the course of my PhD.

In addition, I wish to thank the more recent senior members of the Abankwa lab **Dr. Rohan CHIPPAKATTI** and **Dr. Karolina PAVIC** for helping out with troubleshooting experiments, data analysis and literature expertise. I will also like to thank my fellow PhD students **Pelin KAYA** and **Candy STEFFEN** for being such kind colleagues and a delight to converse with.

I would like to thank all the current and previous members of the department of life sciences and medicine (DLISM) with whom I had the opportunity to meet and interact with during my visits to BT2. Special thanks to **Prof. Iris BEHRMANN**, **Sergio ALVAREZ** and **Alexandre SALSMANN** who have been so helpful with my nonprofits efforts to improve biomedical research in my home country of Nigeria. Special thanks go to **Dr. Raquel MACHADO**, Lis's former postdoc for her friendship, support and all round positivity. Also, I will like to thank **Dr. Sotirios GALTSIDIS** who was always helpful troubleshooting experiments. I enjoyed chatting with you both on stimulating and wide ranging topics on science and society. As we were often isolated from the rest of the department at BT2, the friendships I formed with fellow PhD students from the Signal Transduction Group particularly **Nadege Wendkouni MINNOUNGOU** and **Tijana RANDIC** was really helpful in going through this exciting but challenging period. I also wish to thank all the administrative staff at the DLISM and the office of doctoral education particularly **Caroline HERFROY**, **Stephanie CUGNACH** and **Magali GUILLAUME** respectively for facilitating the day to day activities and for organizing and taking care of trips to conferences and managing orders.

This acknowledgement will be incomplete without the mention of the people in my private life who have helped keep me healthy, safe and made me feel loved. First on this list is my beloved wife and life partner **Grace Ebi-ojo EKELE**. You have been and continue to be my rock through thick and thin, you helped console me far from home and all our loved ones when daddy passed and

continue to support me in every possible way. You have given me the greatest gift of all, a family and a future. Thank you for enduring my late nights working nonstop, thank you for taking care of our son **Onu Alexander OKUTACHI** after your long workdays as I stay glued to my PC. Thank you for all the happy memories and moments. Indeed, I am lucky to have you both in my life.

To my late dad **James OKUTACHI**, I am thankful for all the love and support throughout my formative years. You taught me to be decent, to dream beyond my immediate circumstances, work hard and be ambitious. The successes of my life so far are chiefly credited to you. You are the model dad and I know you would be proud of me today. Thank you mum **Elisabeth OKUTACHI**, you have always been there for me through the good and tough times, thank you for the unconditional love, the long nights tending to my needs and enduring a very energetic child. Finally, I wish to specially thank all my siblings **McDonald, Christiana, Moses, Victor and Mary** for your endless love and support all these years. Thank you for all the childhood memories and adventures in our small world in Lokoja. I couldn't have hoped for a better family.

Attah mi, Oma mi, iye mi, kpai oya mi, mè má defí olaiye mi'n, u má neke chi ewundun.

Thank you all.

Dedication

This PhD is dedicated to my wife Grace, my son Onu, my dad James who passed 5 months into my PhD and my mum Elisabeth.

“Education, then, beyond all other divides of human origin, is a great equalizer of conditions of men—the balance wheel of the social machinery.”

Horace Mann, 1848

List of Abbreviations

A2ML1	Alpha-2-macroglobulin-like 1
AKT	Protein Kinase B
APC	Adenomatous polyposis coli
Arf	ADP ribosylation factors
Arl2	Arf-like protein 2
ATF2	Activating transcription factor 2
AUC	Area under the curve
BAD	Bcl-2 associated death promoter
BAX	Bcl-2 associated x protein
Bcl-2	B-cell lymphoma 2
BCR-ABL	Breakpoint cluster region protein - Tyrosine protein Kinase ABL1 fusion gene
B-Raf	Rat-1 fibroblast kinase B homolog
BRET	Bioluminescence resonance energy transfer
CaM	Calmodulin
CaMeRas	Calmodulin-K-Ras4b fusion biosensor
cAMP	Cyclic adenosine monophosphate
CBL	E3 ubiquitin-protein ligase CBL
CDC25	Cell division cycle 25, a dual specific phosphatase first isolated from yeast
Cdc42	Cell division control protein 42 homolog
CDK4	Cyclin dependent Kinase 4
CDKs	Cyclin dependent Kinases
cGMP	Cyclic guanosine monophosphate
CIP2A	Cancerous inhibitor of PP2A
C-jun	Jun proto-oncogene
CRC	Colorectal cancer
CSCs	Cancer stem cells
CTLA4	cytotoxic T-lymphocyte-associated protein 4
DSS	Drug sensitivity score
DUSP	Dual specificity phosphatase
EC₅₀	Half maximal effective concentration

List of abbreviations

EGFR	Epidermal growth factor receptor
ERK	Extracellular signal regulated kinase
FGFR	Fibroblast growth factor receptor
FLIM	Fluorescence life-time imaging microscopy
FRET	Fluorescence resonance energy transfer
FTase	Farnesyl transferase
FTIs	Farnesyl transferase inhibitors
GAPs	GTPase activating proteins
GDP	Guanosine 5' diphosphate
GEFs	Guanine nucleotide exchange factor
GGTase1	Geranylgeranyltransferase
GGTIs	Geranylgeranyltransferase inhibitors
GRB2	Growth factor receptor-bound protein 2
GTP	Guanosine 5' triphosphate
GTPases	Guanosine triphosphatases
HCC	Hepatocellular carcinoma
HEAT	Hungtingtin Elongation factor 3/ PP2A A/TOR1
HIF-1	Hypoxia inducible factor 1
H-Ras	Harvey rat sarcoma viral oncogene homolog
HVR	Hypervariable region of Ras proteins
IC₅₀	Half maximal inhibitory concentration
ICMT	Protein-S-isoprenylcysteine O-methyl transferase
IEX-1	Immediate early response gene X-1
IKK	IkappaB Kinase
iPSCs	Induced pluripotent stem cells
IRS1	Insulin receptor substrate 1
JNK	Jun amino-(N)-terminal kinase
K-Ras	Kirsten rat sarcoma viral oncogene homolog
LCMT-1	Leucine Carboxyl Methyl Transferase 1
LUAD	Lung adenocarcinoma
LZTR1	Leucine-zipper-like transcriptional regulator 1
MAP2K1	Dual specificity mitogen-activated protein kinase kinase 1
MAP4K3	Mitogen-activated protein kinase kinase kinase kinase 3

List of abbreviations

MAPK	Mitogen-activated protein kinase
MEK	MAPK/ERK Kinase
mTOR	Mammalian target of Rapamycin
mTORC1	mTOR complex 1
NF-κB	Nuclear factor Kappa B
NF1	Neurofibromin 1
N-Ras	Neuroblastoma Ras viral oncogene homolog
NSCLC	Non-small cell lung cancer
OCT4	octamer-binding transcription factor 4
p110α	Phosphatidylinositol-4,5-bisphosphate 3-kinase, catalytic subunit alpha
p21^{CIP1}	cyclin-dependent kinase inhibitor 1
PATs	Palmitoyl acyl transferases
PD1	Programmed death protein 1
PDACs	Pancreatic ductal adenocarcinomas
PDE6D	Phosphodiesterase 6 delta subunit
PDEs	Phosphodiesterases
PDGR	Platelets derived growth factor receptor
PDK1	Protein Kinase D 1
PDL1	Programmed death ligand 1
PI3K	Phosphoinositide-3-kinase
PIP2	phosphatidylinositol 4,5-bisphosphate
PIP3	phosphatidylinositol 3,4,5-trisphosphate
PKC	Protein Kinase C
PM	Plasma membrane
PME1	PP2A methylesterase-1
PP2A	Protein phosphatase 2 α
PROTACs	Proteolysis targeting chimeras
PTEN	Phosphatase and tensin homolog
PTM	Post translational modification
PTPA	Phosphotyrosyl phosphatase activator
PTPN11	Tyrosine-protein phosphatase non-receptor type 11
Rab	Ras-like protein in brain
Rac1	Ras-related C3 botulinum toxin substrate 1
Ral	Ras-like

List of abbreviations

RalA	Ras-like A
RalB	Ras-like B
RalBP1	Ral binding protein 1
RalGDS	Ral guanine nucleotide dissociation stimulus
Ran	Ras-related nuclear protein
Ras	Rat sarcoma (protein)
RASA1	RAS P21 Protein Activator 1
RCE1	Ras converting enzyme 1
Rheb	Ras homolog enriched in brain
Rho	Ras homologus
RIT1	GTP-binding protein Rit1
RTKs	Receptor tyrosine kinases
S6K	Ribosomal protein S6 Kinase beta-1
Sec5	Exocyst complex component SEC5
SET	Suvar/ Enhancer of zeste/ Trithorax
SHC	Src homology 2 domain containing transforming protein
SH-domain	Src homology domain
SHOC-2	Leucine-rich repeat protein
SHP2	Src homology 2 (SH2) domain–containing phosphatase 2
SMAP	Small molecule activator of PP2A
SOS	Son of sevenless
SPRED1	Sprouty-related, EVH1 domain-containing protein 1
SPRY	Sprouty RTK signaling antagonist
Src	Non-receptor protein tyrosine kinase
SREBP	Sterol regulatory element-binding protein
STAT3	signal transducer and activator of transcription 3
TANK	TRAF Family Member Associated NFKB Activator
TBK1	TANK-binding Kinase 1
TILs	Tumor infiltrating lymphocytes
TSC2	Tuberous sclerosis complex 2
UPS	Ubiquitin proteasome system
VEGF	Vascular endothelial growth factor
Wnt	Wingless type

Abstract

Mutations in the KRAS gene are associated with approximately 15% of all human cancers. This makes it one of the most frequently mutated oncogenes known. Whilst recent breakthroughs in Ras drug discovery have led to the FDA approval of the first direct and covalent inhibitor of the KRAS-G12C mutant, the majority of KRAS driven cancers are not G12C mutated. Furthermore, recent studies have identified resistance mechanisms against the new inhibitors. Consequently, research into other direct and indirect Ras inhibition strategies, as well as synergistic drug combination efforts are being vigorously pursued.

In the first part of this thesis, I describe my contributions to the development and characterization of novel PDE6D inhibitors with activity against KRAS driven cancers. PDE6D is a trafficking chaperone of K-Ras that facilitates its dynamic localization to the plasma membrane. Although some progress had been made in identifying lead drug candidates against this protein, an Arl2 dependent PDE6D cargo ejection mechanism continues to hamper progress. We describe the development of **Deltaflexin 1 and Deltaflexin 2**, into which we engineered a 'molecular spring' to improve resilience to Arl2 ejection of PDE6D cargo. We show that these compounds selectively inhibit K-Ras membrane organization and exhibited K-Ras selective anti-proliferative effects against cancer cell lines from colon and breast tissues whilst blocking the 3D spheroid growth of lung and breast cancer cell lines.

In the second part, I describe my main project, the identification of a novel covalent inhibitor of calmodulin (CaM) with anti-cancer activity in K-Ras mutated cancers named **Calmirasone1**. A relevance of the K-Ras/ CaM interaction for the promotion of cancer cell stemness has been previously suggested. We previously showed that the natural product Ophiobolin A (OphA) blocked K-Ras membrane organization in a CaM dependent manner and cancer cell spheroid formation. However, because of the broad toxicity of OphA, its suitability as a tool compound to further study this K-Ras/CaM associated stemness properties is limited. We have therefore characterized a set of benzazulenones with distant chemical similarity to OphA in a battery of assays. We identified Calmirasone1 which exhibits improved CaM affinity and a significantly lower unspecific toxicity relative to OphA. Furthermore, Calmirasone1 selectively blocked K-Ras membrane organization and inhibited the 3D spheroid growth of K-Ras dependent cancer cell lines.

In the third part of this thesis, I assessed the synergistic potential of targeting CaM and protein phosphatase 2A (PP2A) in Ras-MAPK dependent cancer cell lines. PP2A is a tumor suppressor that catalyze the dephosphorylation of multiple targets in the cell. Using specific

Abstract

CaM inhibitors and PP2A agonists as well as the already clinically approved phenothiazines (PTZs), our results from this study suggests that synergistic targeting of CaM and PP2A improves anti-cancer effects and that PTZs combine CaM inhibitory and PP2A re-activating properties in their cancer killing activity.

INTRODUCTION

1. INTRODUCTION

Cancer is the second leading cause of death globally, in 2020, 19.3 million new cases and almost 10 million deaths were estimated for the disease ([Sung et al., 2021](#)). The global burden of cancer is projected to continue to increase due to factors such as lifestyle changes, increased life expectancy and an increasingly aging population ([Sung et al., 2021](#)). With over 70% of cancer mortalities occurring in developing countries whose healthcare systems are often overstretched, the need for innovative approaches to cancer treatment is without question.

Half a century of research in molecular oncology has led researchers to identify many of the genetic alterations that are implicated in cancer development, chief among these being the transformation of proto-oncogenes into oncogenes and the blockade of tumor suppressor gene activity. Several hallmark features of cancer have been extensively characterized ([Hanahan and Weinberg, 2011](#)). This deeper understanding of the disease has led to a surge in the development of targeted therapeutics aimed at the onco-proteins such as the BCR-Abl oncofusion Kinase (Gleevec), B-Raf (Sorafenib, Zelboraf), EGFR (Erlotinib) etc. Unfortunately, some oncogenic proteins such as Ras have remained elusive to direct therapeutic intervention.

Ras proteins were among the earliest identified oncogenes. These proteins have been implicated in approximately 19% of all human solid tumors thus making them the most frequently mutated oncogenes in cancer ([Prior et al., 2020](#)). After almost 40 years of intense research, recent breakthroughs have led to the clinical development of the first direct and covalent inhibitors of the K-RasG12C mutant of which Amgen's molecule, sotorasib recently received FDA approval ([Moore et al., 2020](#), [Amgen, 2021](#)). Importantly, whilst this represents a major breakthrough in Ras drug development, the majority of K-Ras driven cancers are not G12C mutated. Furthermore, recent studies have identified resistance mechanisms against these new inhibitors ([Tanaka et al., 2021](#)). Hence, research into other direct and indirect Ras inhibition strategies as well as synergistic drug combinations are being vigorously pursued.

In the first part of this thesis, we developed and characterized novel PDE6D inhibitors with activity against K-Ras driven cancers. PDE6D is a trafficking chaperone of K-Ras that facilitates its dynamic localization to the plasma membrane ([Chandra et al., 2011](#)). Although some progress had been made in identifying early leads against this protein, an Arl2 dependent PDE6D cargo ejection mechanism continues to hamper progress in efforts to develop viable drug candidates ([Martin-Gago et al., 2017](#)). To this end, we developed and evaluated novel PDE6D inhibitors with a different design principle across a number of cellular and biochemical assays for their K-Ras mediated anti-cancer activities.

Introduction

In the second part of this thesis, we characterized novel covalent inhibitors of CaM that are able to disrupt the K-Ras/CaM interaction in cells. Recent evidence suggests that K-Ras interacts with CaM to promote cancer cell stemness by suppressing non canonical frizzled-8 mediated Wnt signaling (Wang et al., 2015b). Indeed, CaM has been recently identified as a *bona fide* chaperone protein able to facilitate the dynamic distribution of K-Ras alongside PDE6D (Grant et al., 2020b, Agamasu et al., 2019, Chandra et al., 2011). Ser181 of K-Ras plays an important role in this interaction since phosphorylation of this residue by treatment with prostratin compromises K-Ras binding to CaM and suppressed K-Ras mediated tumorigenicity (Wang et al., 2015b). Also, Ophiobolin A (OphA), a covalent inhibitor of CaM was shown to block K-Ras nanoclustering and sphere formation in K-Ras mutated cancer cell lines (Najumudeen et al., 2016). However, OphA exhibits unspecific toxicity against numerous targets. Hence, our goal here was to develop OphA-like compounds with improves CaM specific activity and cellular activity against K-Ras driven cancers.

In the third part of this thesis, we assessed the synergistic potential of targeting Ras mediated pathways through the combination of CaM inhibitors and Protein phosphatase 2 α (PP2A) reactivation. PP2A is a tumor suppressor that catalyze the dephosphorylation of multiple targets in cells, the activity of PP2A is down-regulated in many cancers (Sangodkar et al., 2016). Previous reports have indicated that PP2A reactivation blocks the growth of Ras driven cancers (Kauko et al., 2018). To this end, we explore the synergistic potential of blocking both CaM and re-activating PP2A. We assessed phenothiazines, a class of antipsychotic drugs as well as single agent CaM inhibitors and PP2A agonists in a panel of cells lines within this study.

Conclusively, the findings of our PDE6D study have formed the basis for the development of third generation PDE6D inhibitors. From the CaM study, a new tool compound Calmirasone1 has been identified which can be applied in unravelling K-Ras/CaM associated cancer stemness characteristics in subsequent studies. Furthermore, our results from the synergism study suggest that phenothiazines can integrate the synergistic activities of CaM inhibition and PP2A activation. Importantly, during the course of this thesis, we developed a new highly sensitive live-cell BRET based compound screening assay for the identification and characterization of Ras isoform specific protein-protein interaction (PPI) disrupting small molecules.

1.1 Ras Small GTPases

Small guanosine triphosphatases (GTPases) are a group of proteins defined by their ability to bind GTP and hydrolyze it into GDP, the so-called GTP/GDP cycle (Bourne et al., 1991). Whilst small GTPases are biochemically and functionally similar to the α -subunit of heterotrimeric G proteins, they differ from G-proteins due to their ability to function as monomeric units (Claing, 2013). A total of 167 members of the small GTPase family have been identified in humans till date (Figure 1), these proteins are subdivided on the basis of sequence and functional similarities into five families consisting of 39 Ras proteins, 30 Arf proteins, 22 Rho proteins, 65 Rab proteins, 1 Ran protein and 7 unclassified proteins (Figure 1) (Rojas et al., 2012, Liu et al., 2017).

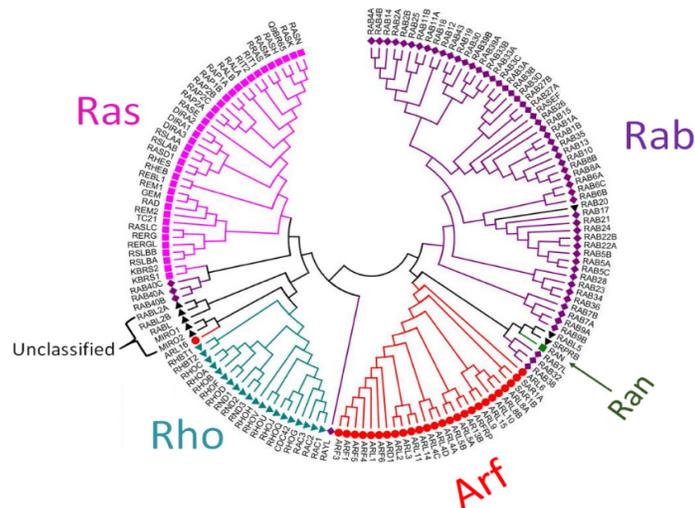

Figure 1. Phylogeny of the Ras Small GTPase Super-family. Adapted from (Qu et al., 2019)

The Ras family members were the first to be identified in this superfamily. They function primarily as signaling nodes that mediate cellular responses to many extracellular stimuli and are known to regulate cellular differentiation, proliferation, morphology and apoptosis through interactions with a variety of downstream effectors, some of the best known proteins in the Ras family are K-Ras, H-Ras and N-Ras (Karnoub and Weinberg, 2008). Rho family members are known for their central role in actin cytoskeletal remodeling and cell polarity. Some well-known and extensively studied members of the Rho family include RhoA, Rac1 and Cdc42 (Etienne-Manneville and Hall, 2002, Hall, 1998). The Rab family is the largest in the Ras superfamily in humans, they are best

Ras protein structure

known for their role in vesicle formation, movement and fusion as well as vesicular cargo trafficking (Pereira-Leal and Seabra, 2001, Segev, 2001). The 30 member-strong Arf family in addition to facilitating the bi-directional vesicular trafficking of cargo also modulate lipid membrane composition, ciliogenesis, energy metabolism and transcriptional regulation (Donaldson and Jackson, 2011, Sztul et al., 2019). The Ran protein is the only member of its family, this protein is present in all eukaryotes and plays a key role in nuclear transport (Weis, 2003). Importantly, Ran acts as a positional marker of the genome to regulate multiple aspects of the eukaryotic cell cycle (Weis, 2003).

1.1.1 Ras protein structure

Four (4) ubiquitously expressed Ras isoforms derive from three (3) distinct Ras genes in humans. The HRAS gene encodes H-Ras protein, NRAS encodes N-Ras protein and the KRAS gene encodes two alternative splice variant proteins K-Ras4a and K-Ras4b (Ahearn et al., 2018). These proteins show a high degree of sequence identity (between 82-90% amino acid sequence homology). However, only the first 82 amino acids of all 4 Ras isoforms exhibit 100% sequence homology (Ahearn et al., 2018). This structural region contains the G – domain which is involved in GTP binding/hydrolysis as well as the switch I (residues 32-38) and switch II (residues 60-75) regions that serve as allosteric determinants of Ras effector binding (Vetter and Wittinghofer, 2001). Whilst the majority of the sequence divergence of Ras proteins reside in the hypervariable region (HVR), a second level of sequence variation exists from amino acids 86-166 (Zhou et al., 2016). This region which has a 78% sequence identity has been shown to contain the allosteric functionality that plays an important role in S II conformation, membrane orientation and the formation of nanoclusters which in turn regulates effector utilization (Parker and Mattos, 2015, Abankwa et al., 2010). Indeed, a third previously unknown switch region (Switch III) which comprises of the β 2- β 3-loop and helix α 5 was identified by Abankwa et al., (Abankwa et al., 2008b). This novel region was also found to play a role in defining the membrane orientation of Ras proteins (Abankwa and Gorfe, 2020). Upon GTP-binding, Switch III undergoes structural rearrangements that leads to an alternative engagement of the helix α 4, two basic residues on helix α 4 then contact membrane lipids leading to the reorientation of the G-domain (Abankwa et al., 2008b). Finally, the HVR consist of roughly 20 amino acids that vary significantly across all Ras isoforms (**Figure 2**). The HVR is essential for the membrane targeting and prenylation of the various Ras proteins (Hobbs et al., 2016). Indeed the sequence variation on the HVR of Ras proteins defines differential post-translational modification and lipidation (Ahearn et al., 2018). Both K-Ras splice variants have polybasic sequences which in addition to farnesylation (K-Ras4b) and a further palmitoylation (K-Ras4a) facilitates membrane

anchorage (Gelabert-Baldrich et al., 2014). In the case of H-Ras and N-Ras, two and one palmitoyl groups are respectively acquired in addition to the farnesylation at the HVR (Ahearn et al., 2018).

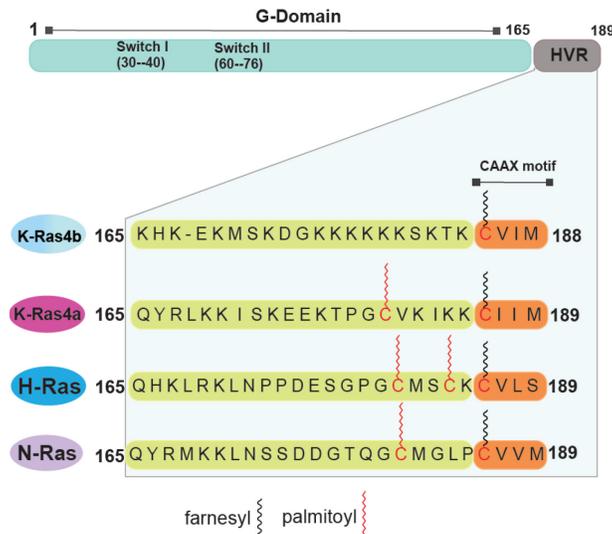

Figure 2. Ras protein structural diversity

Ras proteins have an 82-90% sequence homology in the sequence of the first 165 amino acids. This so called G-domain is responsible for their nucleotide binding and effector engagement functionalities. Ras isoforms differ mostly in the amino acid sequence of their hypervariable region (HVR). This stretch of 24-25 amino acids directs Ras membrane targeting and post translational lipidation.

1.1.2 Ras post-translational modification

Upon cytosolic biosynthesis, Ras proteins and indeed all GTPases containing the CAAX motif are processed by three enzymes; first farnesyl transferase (FTase) catalyses the irreversible farnesylation of the cysteine of the CAAX motif. In the case of K-Ras and N-Ras, an alternative prenylation by geranylgeranyl transferase-1 (GGTase 1) is possible (Whyte et al., 1997). Once prenylated, Ras proteins are targeted to the surface of the endoplasmic reticulum where the Ras-converting enzyme 1 (RCE1) and isoprenylcysteine carboxymethyltransferase (ICMT) catalyzes respectively the cleavage of AAX and carboxymethylation of the cysteine residue (Ahearn et al., 2018, Boyartchuk et al., 1997, Gutierrez et al., 1989). At this point, the CAAX processing and the polybasic lysine residues on the HVR of K-Ras4b is sufficient for membrane targeting by active transport with the support of trafficking chaperone (Hancock et al., 1990).

Ras post-translational modification

N-Ras, H-Ras and K-Ras4a undergoes additional processing by the palmitoylation of additional cysteine residues upstream of the CAAX cysteine; Cys181 for N-Ras, Cys181 and 184 for H-Ras and Cys180 of K-Ras4a (Apolloni et al., 2000, Laude and Prior, 2008). This reversible process is catalyzed by the DHHC family of palmitoyl acyl transferases (PATs), palmitoylation of Cys181 of N-Ras and H-Ras directs sorting from the Golgi apparatus to the recycling endosomes, a necessity for subsequent trafficking to exocytic vesicles destined for the plasma membrane (Figure 3) (Apolloni et al., 2000, Laude and Prior, 2008).

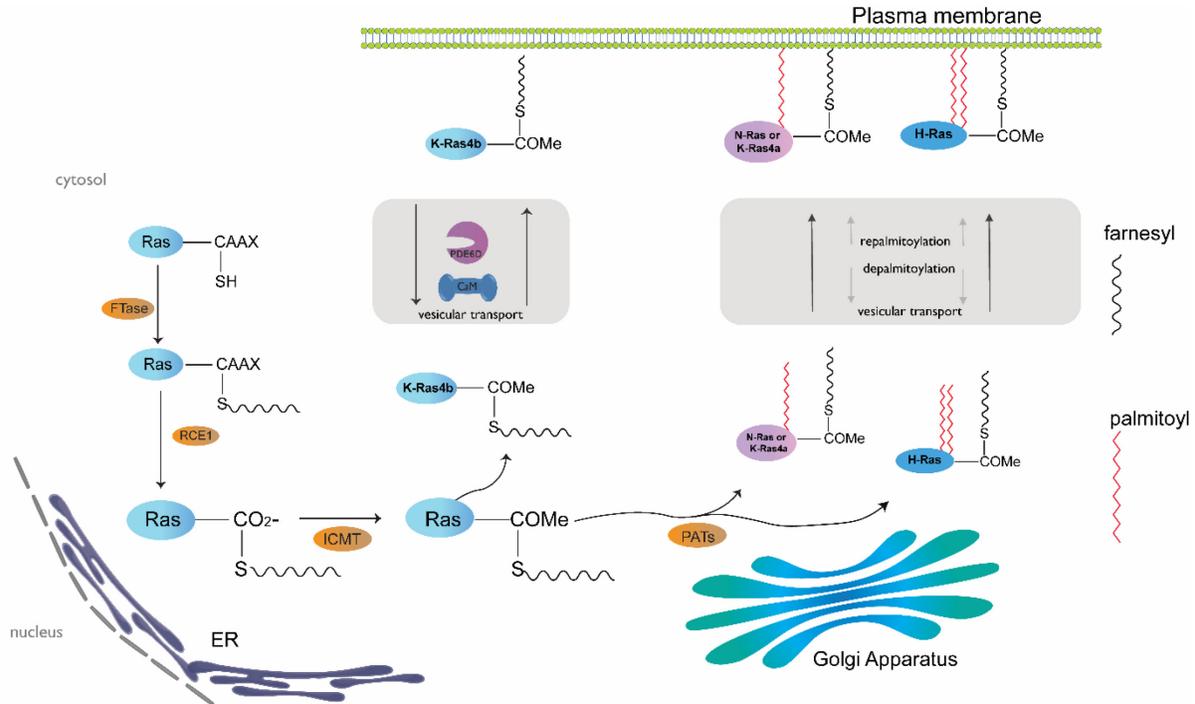

Figure 3. Differential Ras post-translational modification dictates membrane targeting Newly synthesized Ras proteins undergo a series of enzymatic processing at various subcellular locations including the cytosol, endoplasmic reticulum, and Golgi before membrane localization. Farnesyl transferase, Ras converting enzyme and isoprenylcysteine carboxymethyltransferase respectively catalyse the farnesylation, AAX cleavage and carboxy methylation of Ras proteins. Carboxymethylated and farnesylated K-Ras4b is actively transported to the plasma membrane via the recycling endosomes, the trafficking chaperones PDE6D and CaM are known to play a role in modulating K-Ras membrane localization and dynamic distribution. Further processing of the other Ras isoforms N-ras, K-Ras4A and H-Ras on the Golgi enhance their respective membrane targeting via the vesicular transport system.

In addition to the differential palmitoylation of Ras proteins due to their HVR structural variation, Ras proteins undergo a series of additional post-translational modifications on the G-domain (Glucosylation, Sumoylation, ADP-Ribosylation, Acetylation, Ubiquitination and Nitrosylation) (Baker et al., 2013, Yang et al., 2012, Williams et al., 2003, Herrmann et al., 1998).

Ras membrane interaction and cellular localization

Phosphorylation of the G-domain has also been reported (e.g Y32 Y64 and Y137) (Bunda et al., 2014). Whilst the HVR can undergo phosphorylation and cis-trans isomerization (Ahearn et al., 2018). Ubiquitination have also been found to be another level of differential Ras protein post-translational modification (Hobbs et al., 2016). The mono and/or di-ubiquitination of H-Ras was shown to facilitate its internalization into endo-membranes thus limiting H-Ras mediated Raf effector engagement (Jura et al., 2006). Importantly, H-Ras ubiquitination on K117 accelerates nucleotide exchange and activation (Baker et al., 2013). N-Ras as well as K-Ras4b are also mono/di-ubiquitinated whilst the mono-ubiquitination of K-Ras4b at K147 was shown to increase effector engagement without enhancing K-Ras4b subcellular localization, the ubiquitination deficient K-RasG12V exhibited reduced oncogenic activity (Sasaki et al., 2011). Following the present evidence, it is plausible to posit that the differential ubiquitination of Ras proteins distinctly affect the Ras isoforms which may result in unique functional consequences. Finally, acetylation is another PTM that occurs at K104 of K-Ras4b, this modification is proposed to disrupt SII conformation, GEF-mediated activation and the reduction of effector activation and oncogenic potential (Yang et al., 2012). So far, acetylation has only been documented for K-Ras (Yang et al., 2012). It therefore remains to be seen if a similar process occurs with the other Ras isoforms.

1.1.3 Ras membrane interaction and cellular localization

The presence of polybasic groups and palmitoyl lipid groups on Ras proteins enables reversible interactions with the plasma membrane and facilitates dynamic associations with a number of subcellular compartments (Prior and Hancock, 2012). K-Ras exhibits a short residency on the PM (a few minutes) and the net negative charge of the PM is responsible for the accumulation of K-Ras on its surface (Prior and Hancock, 2012). A consequence of this short residency is the apparent absence of an intrinsic capacity for K-Ras to be trafficked by classic membrane carriers (Misaki et al., 2010). Palmitoylated Ras proteins on the other hand associate more stably with the PM and are thus trafficked post-Golgi association via membrane carriers like the recycling endosomes to the PM (Misaki et al., 2010).

In addition to plasma membrane and ER/Golgi complex localization, a number of other subcellular compartments accessible to Ras proteins have been identified (Prior and Hancock, 2012, Bivona et al., 2006). The recycling endosomes which plays a critical role in endocytosis and growth factor signaling as well as mitochondrial localization of K-Ras which triggers apoptosis upon PKC mediated S181 phosphorylation are well established alternative point of K-Ras localization (Prior and Hancock, 2012, Bivona et al., 2006). Importantly, recent studies have established the central role of Ras chaperone proteins particularly the delta subunit of phosphodiesterase 6 (PDE6D) and the master calcium signal regulatory protein CaM in promoting K-Ras reversible translocation

between the subcellular space and plasma membrane (Chandra et al., 2011, Sperlich et al., 2016, Agamasu et al., 2019, Grant et al., 2020b).

1.1.4 Ras nanoclustering

Ras anchorage to the plasma membrane is pre-requisite for effector engagement and downstream signaling. The HVR is responsible for directing this membrane localization (Abankwa et al., 2008a). Ras proteins form distinct non-random proteo-lipid clusters on the PM called nanoclusters (Figure 4) (Prior et al., 2003). The membrane raft hypothesis evidenced by the work of the Hancock group established some critical hallmark features of Ras nanoclusters namely that; (1) Ras isoforms segregate laterally into distinct dynamic nanoclusters potentiated by their intrinsic HVR differences. (2) The nanoclusters have a 9nm radius containing up to 7 Ras proteins per cluster. (3) Ras nanoclusters have an average lifetime that vary between 0.1 s and 1 s in its inactive and active states respectively and that (4) approximately 40% of Ras proteins are immobilized nanoclusters whilst the remaining proteins freely diffuse as monomeric units (Abankwa and Gorfe, 2020).

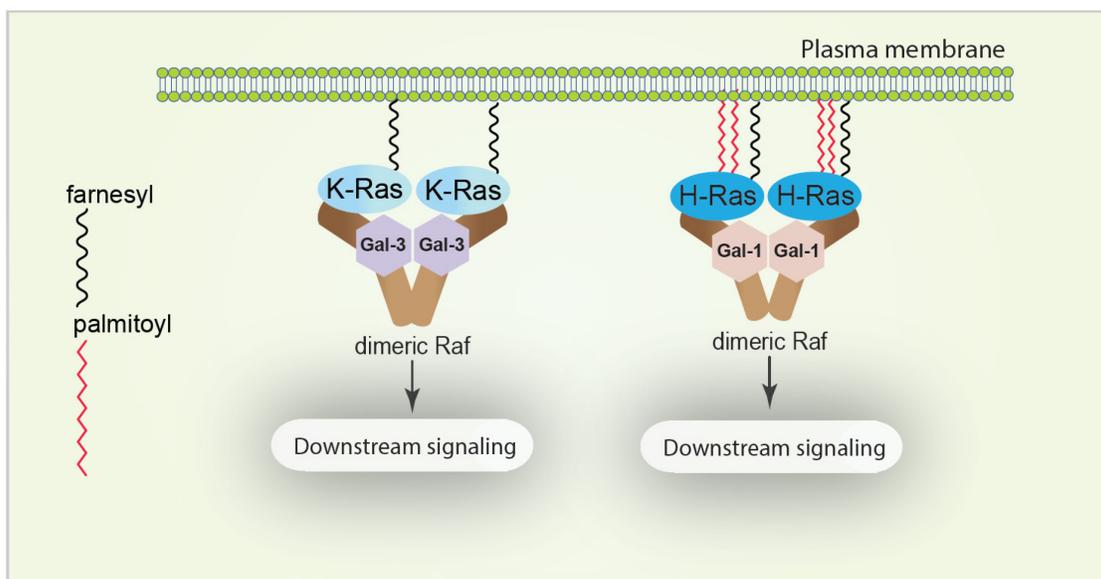

Figure 4. Ras proteins form distinct nanoclusters.

Ras isoforms form distinct proteo-lipid nanoclusters which facilitates isoform specific downstream signaling. Various proteins such as galectin-3 and galectin-1 have been reported to facilitate the K-Raf/Raf and H-Ras/Raf interface respectively.

Ras nanoclusters are required for the recruitment and activation of Ras effectors such as Raf proteins. In fact, previous studies showed that Ras monomeric units fail to activate Raf and various Ras dependent signaling networks (Plowman et al., 2008). Thus, proteins such as galectin-3 and galectin-1 which are known to be important for the respective nanoclustering of K-

RasG12V and H-RasG12V have emerged as attractive drug targeting strategies in Ras driven cancers (Shalom-Feuerstein et al., 2008, Blazevits et al., 2016, Abankwa and Gorfe, 2020).

1.1.5 Cellular Ras activation, signaling and effector engagement

Ras proteins signal downstream of the receptor tyrosine kinases (RTKs) to facilitate key signaling pathways such as the Ras-MAPK-ERK pathway, the PI3K-AKT-mTORC1 pathway as well as the less characterized RalGDS signaling pathway (**Figure 6**). In normal cells, these pathways are important in controlling critical functions such as growth, proliferation and survival (Downward, 2003, Neel et al., 2011).

The first step in “normal” Ras signaling involves the binding of extracellular growth ligands to a group of transmembrane RTKs e.g the epidermal growth factor receptor (EGFR), fibroblast growth factor receptors (FGFR) or platelet derived growth factor receptors (PDGR). Binding of RTKs to these ligands induces receptor dimerization and phosphorylation (Downward, 2003). The autophosphorylated intracellular domain of the RTKs then binds to the SH2 domain of an adaptor protein called growth-factor-receptor-bound protein 2 (GRB2). GRB2 through its SH3 domain recruits the guanine nucleotide exchange factor (GEF) son of sevenless (SOS) (Downward, 2003). Because Ras small GTPases can only elicit downstream signaling in their GTP bound form, the replacement of GDP with GTP serves as a binary switching mechanism for the regulation of cellular growth signals (Hennig et al., 2015). Upon binding to GTP, Ras proteins undergo significant conformational changes that facilitates effector recruitment for subsequent downstream signaling (Wennerberg et al., 2005). Importantly, after effector recruitment, GTP is hydrolysed by Ras proteins via their intrinsic GTPase activity and the action of GTPase activating proteins (GAPs) that enhances the intrinsic GTPase activity of Ras proteins (e.g neurofibromin 1 aka NF1). By this means, Ras proteins are able to cycle between an “on” and “off” state dictated by its nucleotide binding status (**Figure 5**) (Hennig et al., 2015).

1.1.5.1 RAS/MAPK signaling pathway

Canonical MAPK signaling (also called the Ras-Raf-MEK-ERK signaling pathway) is central to cellular processes such as proliferation, differentiation, apoptosis, angiogenesis etc. (Guo et al., 2020). In this cascade of events involving several mitogen activated protein kinases (MAPKs), GTP-bound Ras promotes Raf dimerization and phosphorylation, this induces Raf kinase activity which is crucial for the phosphorylation of Raf substrates MEK1 and MEK2 (Nussinov et al., 2020). Raf kinase domain dimerization is pre-requisite for full activation of Raf (Zhang et al., 2021, Rajakulendran et al., 2009). Like most other kinases, wild-type Raf proteins remain mostly in a guarded auto-inhibitory state via a mechanism that protects against unregulated activation,

signaling and even degradation of Raf proteins by shielding the Raf kinase dimerization surface (Nussinov et al., 2020). 14-3-3 proteins are universally expressed regulatory scaffold proteins known to be critical for the autoinhibition of Raf proteins (Liau et al., 2020, Zhang et al., 2021). Raf proteins contains two 14-3-3 recognition motifs (Kohler and Brummer, 2016). Phosphorylation of Ser729 (B-Raf), Ser621 (C-Raf) and Ser582 (A-Raf) on the C-terminal tail is known to promote Raf activation (Chong and Guan, 2003, Zhang et al., 2021). Conversely, phosphorylation of Ser365 of the B-Raf CR2 loop, Ser259 (C-Raf) and Ser214 (A-Raf) inhibits Raf activation (Chong and Guan, 2003, Zhang et al., 2021). Recent evidence from a cryoelectron microscopy study confirm that the interaction of 14-3-3 dimers with the two phosphorylation sites keep Raf proteins in the auto-inhibited state (Park et al., 2019).

Following Ras activation, the cascade proceeds with MEK-mediated activation of ERK1 and ERK2 (Park et al., 2019). ERK serine/threonine kinase activity both phosphorylates a range of nuclear transcriptional factors to modulate cellular growth and participate in the negative feedback regulation of the entire cascade by phosphorylating upstream components such as SOS or C-Raf and by altering transcription of dual specific phosphatase (DUSP) family as well as the sprouty (SPRY) family of proteins (Owens and Keyse, 2007, Lake et al., 2016).

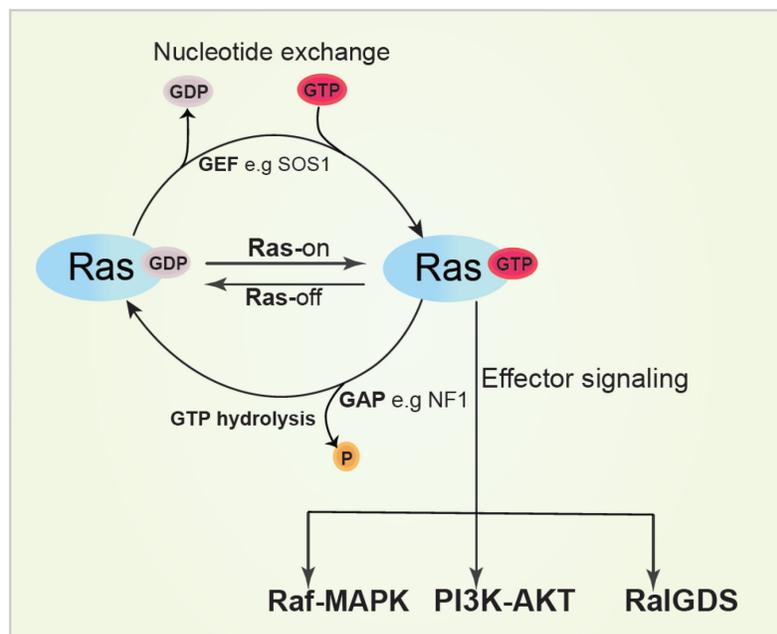

Figure 5. Ras binary switching through GEFs and GAPs activity.

1.1.5.2 The PI3K/AKT signaling pathway

Another pathway downstream of Ras relevant in the regulation of cell proliferation, differentiation, metabolism, migration, mobility and apoptosis is the PI3K/AKT/mTOR signaling pathway.

Dysfunctional PI3K/AKT signaling is generally considered a hallmark cancer feature (Thorpe et al., 2015). Through the activity of phosphatidylinositol-4-5-bisphosphate-3-kinases (PI3Ks), protein kinase B (AKT) and eventually the mechanistic target of rapamycin (mTOR) is activated via a series of phosphorylation events. Upon activation, PI3K phosphorylates membrane bound PIP2, converting it to PIP3 to activate the signaling cascade. PIP3 acts as a secondary lipid messenger that recruits both AKT and its serine/threonine kinase activator PDK1 to the plasma membrane through direct binding to their PH domains resulting in the consequent downstream signaling pathway (Zhang et al., 2019, Castellano and Downward, 2011). The phosphatase tumor suppressor and tensin homolog (PTEN) dephosphorylates PIP3 to PIP2 thus terminating the signal and completing the cycle (Castellano and Downward, 2011). PI3K-AKT signaling promotes growth and survival via many mechanisms including the inhibition of pro-apoptotic Bcl-2 family members BAD and BAX as well as the negative regulation of the transcriptional factor NF- κ B which results in transcription of pro-survival and anti-apoptotic genes (Engelman et al., 2006, Duronio, 2008). AKT also phosphorylates TSC2 thus inhibiting the TSC1/TSC2-mediated inhibition of Rheb GTPases which are essential for the activation of the mammalian target of rapamycin (mTOR). The mTORC1/mTORC2 protein complexes are important in regulation various anabolic processes such as ribosome biogenesis, protein biosynthesis, nutrient uptake and autophagy. Importantly, mTOR signaling plays a significant role in the development of age-related diseases such as neuropathies and cancer (Cornu et al., 2013).

1.1.5.3 The RalGDS pathway

The least understood Ras effector signaling pathway is the Ras-like (Ral) guanine dissociation stimulus (RalGDS) pathway (**Figure 6**). Similar to Ras proteins (46-51% sequence homology), the two Ral proteins (RalA and RalB) can interact with multiple downstream effectors when GTP-bound (Neel et al., 2011). Ral proteins through the 2 components of the octameric exocyst complex Sec5 and Exo84 regulate cellular exocytosis (Wu et al., 2008). This exocyst function facilitates movement and tethering of post-Golgi secretory vesicles to the plasma membrane before exocytic fusion. Indeed, this exocytic function has been implicated in a number of cancer associated cellular processes such as cell migration and tumor cell invasion (Spiczka and Yeaman, 2008).

Additionally, RalGDS and/or Ral activation is involved in Ras-mediated activation of various transcriptional factors including the phosphorylation and activation of c-Jun through JNK MAPK activation, ATF2 and STAT3 through Src tyrosine kinase activation (de Ruiter et al., 2000, Okan et al., 2001, Goi et al., 2000).

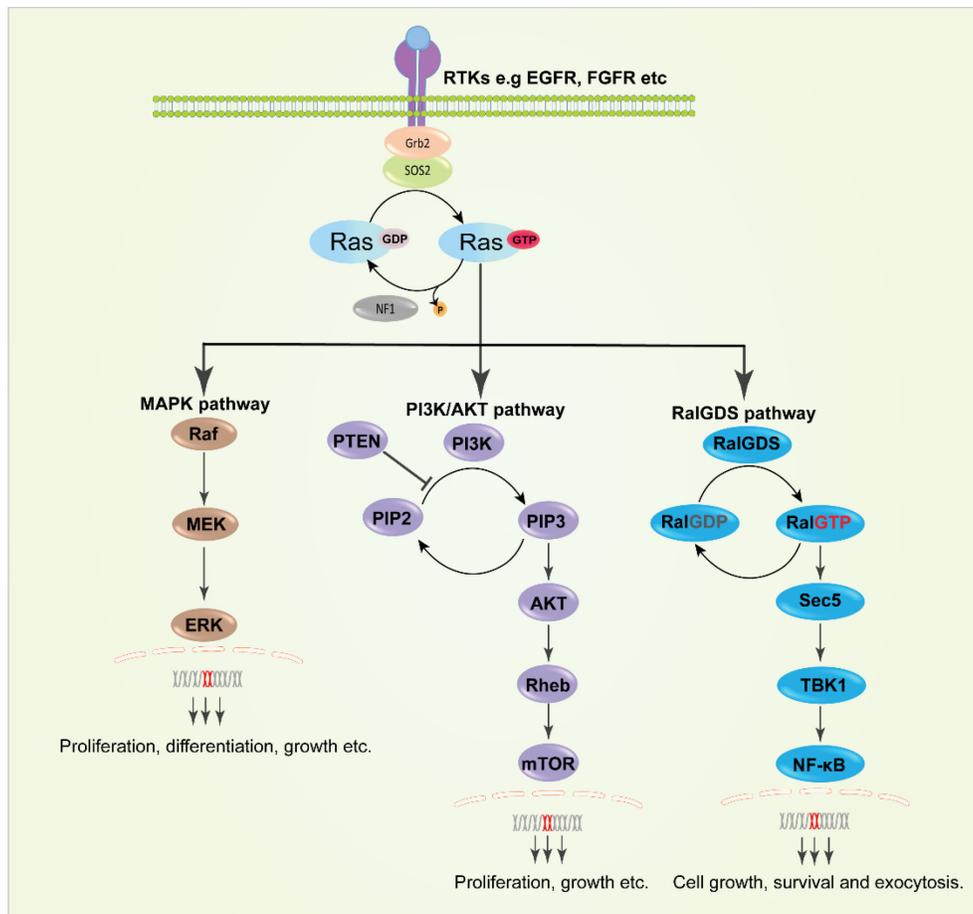

Figure 6. Ras signaling and effector engagement.

Schematic diagram showing 3 major signaling pathways downstream of Ras activation. Membrane bound Ras-GTP facilitates the recruitment of downstream effectors Raf, PI3K and RalGDS for the respective activation of the MAPK, PI3K/AKT and RalGDS signaling cascades that collectively regulate cellular functions like proliferation, differentiation, growth, survival and exocytosis.

Although the Ral-mediated effector signals that regulates these transcriptional factor activation remains sparsely known, Ral-mediated activation of NF- κ B has been sufficiently investigated and was shown to be regulated by Sec5 and not Ral binding protein 1 (RalBP1) (Henry et al., 2000). Activated RalB facilitates the interaction of Sec5 with the TANK-binding Kinase 1 (TBK1), an atypical I κ B Kinase (IKK) (Chien et al., 2006). The recruitment of TBK1 then results in an increase in TBK1 catalytic activity including the direct phosphorylation and promotion of the nuclear localization and activation of NF- κ B (Harris et al., 2006).

1.2 K-Ras in Human Disease

1.2.1 The role of Ras proteins in dysfunctional development

Due to the extensive amount of research data collected in over 4 decades, the relevance of normal Ras functioning for healthy embryonic development and the avoidance of a range of malignancies in adult life is now clearly established. Whilst somatic Ras mutations and/or other Ras pathway protein mutations lead to a wide range of cancers (**Figure 7**). Germline mutations in critical

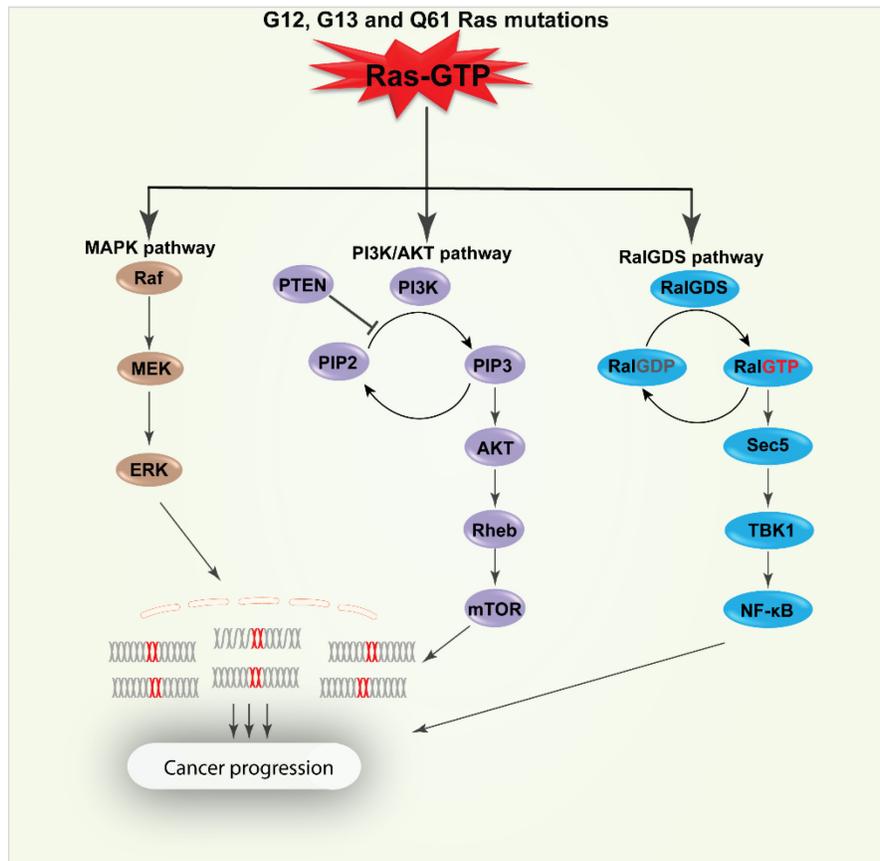

Figure 7. Dysfunctional Ras signaling in Cancer.

components of the Ras-MAPK pathway often result in a number of inherited developmental disease called RASopathies (Rauen, 2013). Although each RASopathy consist of unique phenotypic elements, these syndromes bear many overlapping physiological characteristics including; craniofacial dysmorphia, cardiovascular abnormalities, cutaneous lesions, cognitive and neurological impairments, cardiovascular abnormalities, musculoskeletal abnormalities and a greatly elevated risk of developing malignancies (Rauen, 2013). These diseases (**Figure 8**) include; (1) neurofibromatosis type-1 (NF1) syndrome caused by the haplo-insufficiency of

neurofibromin, a Ras GAP protein central to inactivation of Ras signaling (Cimino and Gutmann, 2018); (2) Noonan syndrome (NS) which can be caused by germline mutations in PTPN11, SOS1, RAF1, KRAS, BRAF, NRAS, MAP2K1, RIT1, SOS2, LZTR1 and A2ML1 (El Bouchikhi et al., 2016); (3) Costello syndrome caused by HRAS activating mutations (Aoki et al., 2016); (4) Craniofaciocutaneous (CFC) syndromes which is caused by BRAF, MAP2K1/2 and KRAS mutations (Aoki et al., 2016); (5) NF1-like syndrome aka Legius syndrome caused by haploinsufficiency of SPRED1 (Brems et al., 2007); (6) Noonan-like syndrome caused by Leucine-rich repeat protein (SHOC-2), a protein that enhances MAP kinase activity by binding and forming a complex with Raf-Ras (Li et al., 2000). Noonan-like syndrome can also be caused by CBL mutations (Cordeddu et al., 2009, Martinelli et al., 2010); (7) Capillary malformation-arteriovenous malformation (CM-AVM) caused by haploinsufficiency of p120 Ras-GAP (RASA1) (Eerola et al., 2003) and (8) Noonan syndrome with multiple lentigines (NSML) caused by PTPN11 and RAF1 mutations (Aoki et al., 2016).

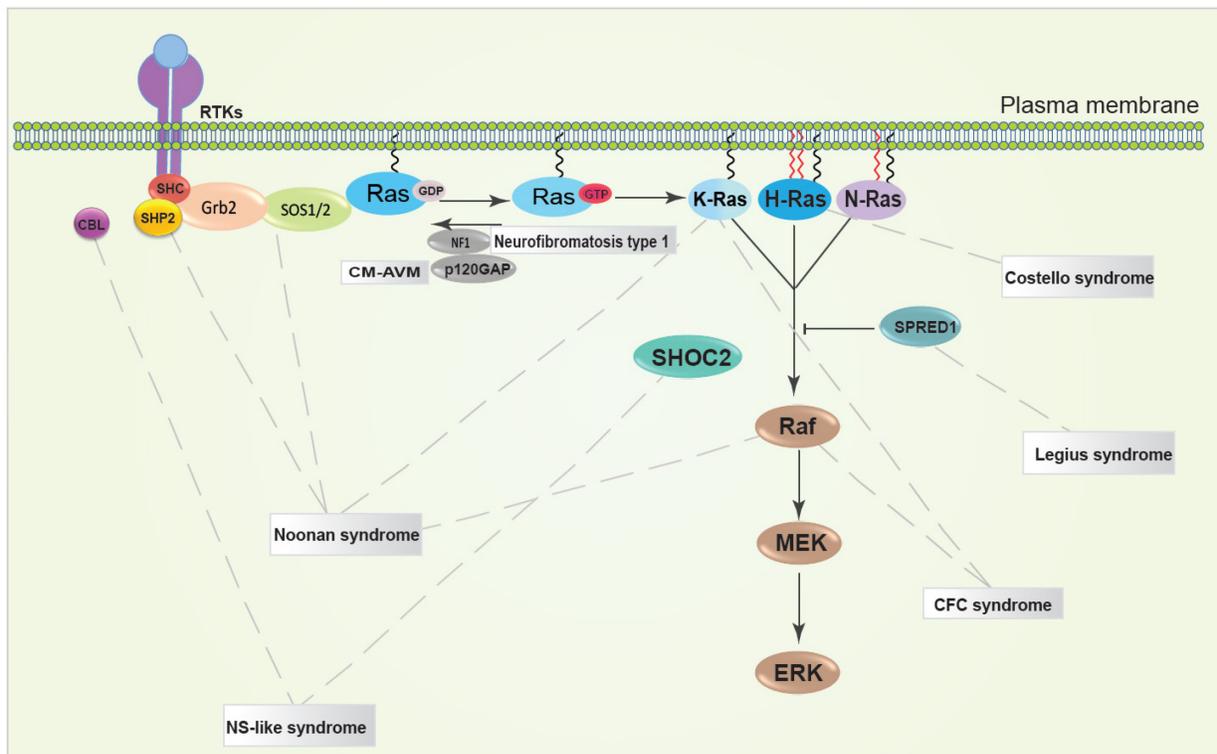

Figure 8. Rasopathies.

Schematic illustration depicting the Ras/MAPK signaling pathway and various effector germline mutations associated with the development of Rasopathies.

RAS MUTATIONS IN CANCER

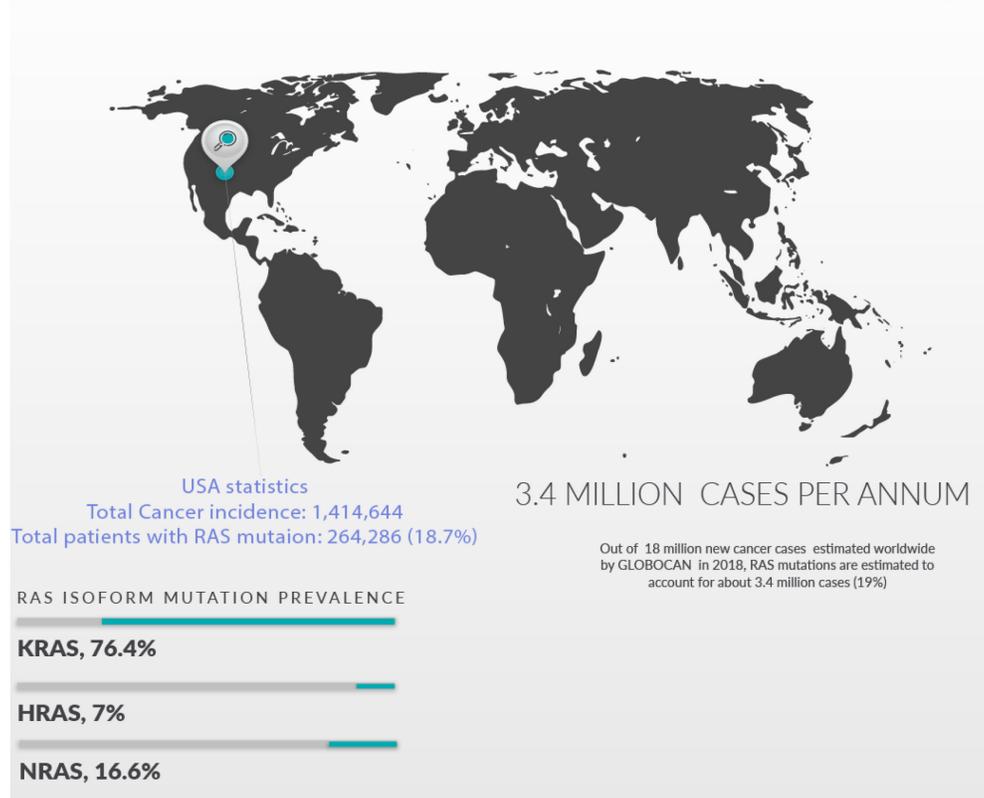

Figure 9. Epidemiology of Ras mutations in cancer.

According to GLOBOCAN, over 18 million cancer cases are reported annually, Ras mutations make up about 19% of these cancers with K-Ras, H-Ras and N-Ras mutations having a 76.6%, 7% and 16.6% of the total Ras mutated cancer burden of 3.4 million (Prior et al., 2020).

The majority of Ras mutated cancers occur in the pancreas (pancreatic ductal adenocarcinomas (PDAC)), colon (colorectal cancer (CRC)), lung (lung adenocarcinomas (LUAD)) and skin (melanomas) (Moore et al., 2020). Interestingly, various Ras isoforms exhibit tumor tissue-type preferences. For instance, PDAC (86%), LUAD (32%) and CRC (41%) are predominantly KRAS driven with the G12 mutation also showing a clear prevalence (Figure 10) (Moore et al., 2020). NRAS mutations on the other hand accounts for 29% of melanomas with the Q61 codon point mutation being the preferred activation mutation in these cancer types (Cancer Genome Atlas, 2015b). Conversely, H-Ras mutations are more common in head and neck cancers (5%) and bladder cancer (4%) albeit at a significantly lower frequency in comparison to K-Ras and N-Ras mutation dominated tissue types (Cancer Genome Atlas, 2015a, Robertson et al., 2017).

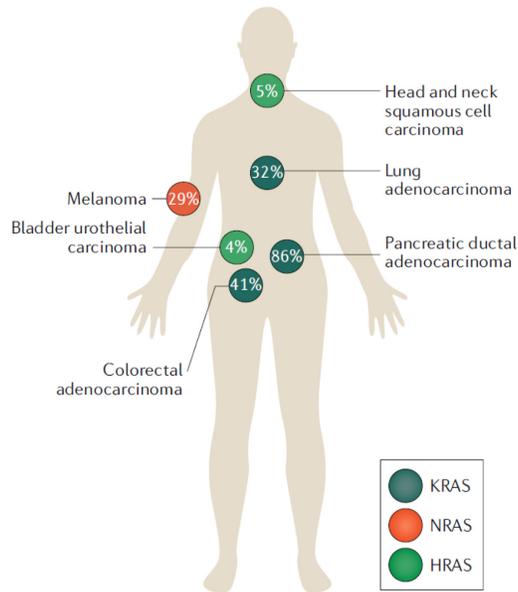

Figure 10. Ras Isoform mutation prevalence and tissue specificity. Adopted from (Moore et al., 2020)

The frequency of Ras isoform mutation and the tissue specificity of the Ras isoform mutation prevalence differ across human cancers. The above figure illustrates the tissue distribution and mutational frequency of the Ras isoforms in human cancers.

For long, evidence of differential and unequal patterns in Ras isoform oncogenicity, patient survival data as well as tissue preference has led the Ras research community to posit that Ras isoforms exhibit critical differences in their cancer causing abilities (Prior and Hancock, 2012, Bournet et al., 2016, Blons et al., 2014, Li et al., 2018). In fact, Prior et al recently proposed that the interplay between three main factors determine if conditions are optimal for Ras driven oncogenesis and perhaps even explain isoform and tissue specificity namely; (1) Ras gene dosage which is defined by relative expression levels and activation states; (2) isoform specific signaling and corresponding mutational status and (3) the cellular and tissue context that contributes and/or dictates the genetic, epigenetic and proteomic landscape upon which Ras networks elicit their signaling effects (Prior et al., 2020). Consistently, unravelling this complex interplay will be central in explaining this not fully understood pattern of inequality displayed by Ras proteins.

Evidence for a varied amount of activated Ras protein population (between 30% to 90%) and a difference in activation stability depending on the nature of the Ras mutation (i.e whether the mutations cause Ras proteins to cycle faster or become GAP-insensitive) coupled with differential Ras isoform expression levels (sometimes reaching over 100-fold difference between isoforms

K-Ras as a driver of cancer stemness

and across tissue types), all point to the importance of Ras gene dosage in defining signaling capacity difference (Li et al., 2018, Prior et al., 2020, Newlaczyl et al., 2017). These differences create a window of permissiveness that is optimal for oncogenic development which may change as tumors progress and acquire resistance to therapeutic interventions (Prior et al., 2020).

Furthermore, the differential localization of Ras proteins within the subcellular space as well as their tendencies to form distinct nanoclusters influences their effector engagement patterns (Zhou and Hancock, 2015, Abankwa and Gorfe, 2020). For instance, in vitro studies have revealed some distinct binding preferences within the Ras-Raf interaction with B-Raf being selective for K-Ras engagement whilst C-Raf showed a clear preference for H-Ras binding (Terrell et al., 2019). Importantly, Galectin 1 and 3 has been shown to respectively act as accessory proteins within the K-Ras/B-Raf and H-Ras/C-Raf interaction interface and therefore plays an important and potentially druggable role in the reported isoform specific signaling (**Figure 4**) (Abankwa and Gorfe, 2020).

1.2.2 K-Ras as a driver of cancer cell stemness

First proposed over 40 years ago, the cancer stem cell (CSC) theory states that a small subset of the tumor population is responsible for fueling the tumor's growth and that this CSC population often evades classic therapeutic intervention (O'Brien et al., 2007). In practice, the CSC theory nicely supports clinical observations, particularly the frequently observed resurgence of tumors after initial seemingly successful treatments (**Figure 11**) (Batlle and Clevers, 2017, Chen et al., 2012). CSCs possess characteristics of normal stemcells including the capacity for self-renewal and differentiation in addition to their ability to initiate tumors. A number of cellular markers such as CD24, CD44, CD133 etc. are used to identify and enrich for the CSC sub-population (Yu et al., 2012). Similarly, a signaling network involving Wnt/ β -catenin, Notch, Hedgehog and microRNAs is known to control the CSC phenotype (Yu et al., 2012). CSCs have been identified in many cancer types including brain, colorectal, breast and hematological malignancies. Consequently, CSC targeting has emerged as a major strategy in cancer drug development (Yang et al., 2020).

A significant body of evidence supports K-Ras as an important player in the promotion of cancer stemness signaling pathways such as the sonic hedgehog signaling pathway in PDAC and canonical Wnt/ β catenin signaling pathway (Gu et al., 2016, Hwang et al., 2020). Similarly, Oncogenic K-Ras in colon cancer was shown to enhance embryonic stem (ES) cell-like program during colon cancer progression from an adenoma to a carcinoma and also activates CSC properties in APC-mutated cells through the MAPK signaling pathway (Le Rolle et al., 2016, Moon et al., 2014). In fact, the critical role of Ras-MAPK signaling in stemcells is supported by the fact

K-Ras as a driver of cancer stemness

that embryonic stem cell transformation from their naïve to primed pluripotent state is dependent on Ras-MAPK signaling as well as their subsequent proliferation and differentiation during embryogenesis (Blair et al., 2011).

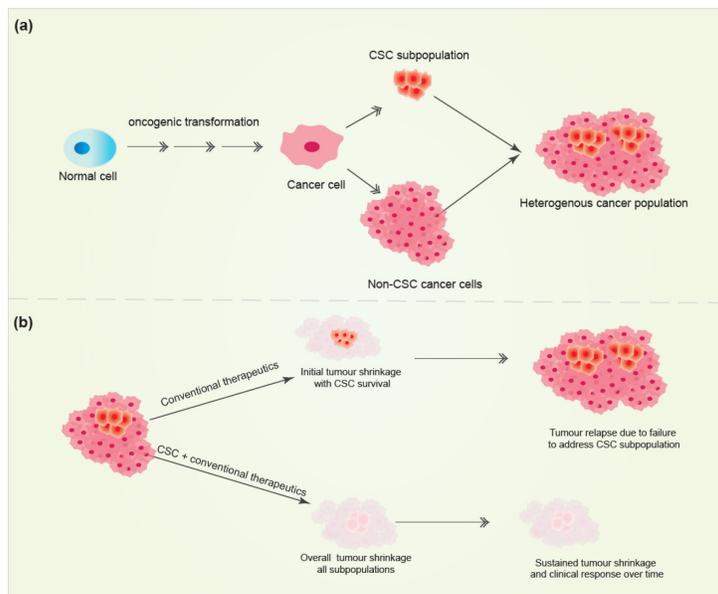

Figure 11. Schematic illustration of the CSC model.

(a) CSCs arise from normal/progenitor cells which undergo and acquire special mutational changes that bestows stem-like characteristics such as self-renewal, differentiation and de-differentiation to a small subset of a tumor population. **(b)** Failure to target the CSCs subpopulation with tradition therapeutic interventions have been proposed to ultimately lead to tumor relapse. Hence, the need to develop CSCs targeting drugs in addition to conventional therapy is likely to improve clinical outcomes.

In addition, induced pluripotent stem cells (iPSCs) derived from patients with K-RasG13C mutations possessed a significantly higher level of stemness marker OCT4 in the heterozygous G13C/wt cells as compared to the homozygous wt/wt populations (Kubara et al., 2018). Interestingly, another study showed that K-Ras (G12D) mutations exclusively caused the increase of the neural stemcell pool in in mouse brain models as similar H-Ras and N-Ras mutations failed to do so thus suggesting a differential isoform specific potential in driving the CSC phenotype (Bender et al., 2015). Importantly, in support of this differential isoform activity, the McCormick group in 2015 showed that K-Ras interacts with CaM to promote cancer cell stemness by suppressing non canonical frizzled-8 mediated Wnt signaling (Wang et al., 2015b). Whilst the underlying mechanisms of K-Ras driven CSC phenotype promotion is still unclear, a growing body of evidence have shown that selective targeting of K-Ras/CaM interaction can be a viable therapeutic strategy against CSCs (Wang et al., 2015b, Najumudeen et al., 2016).

1.3 The K-Ras trafficking chaperone PDE6D

1.3.1 Biochemistry of PDE6D

Phosphodiesterases (PDEs) are a broad family of enzymes consisting of 11 isoenzyme groups and over 50 subunits that catalyse the hydrolysis of cyclic nucleotides and thus play an important role in regulating cellular levels of signaling messengers such as cAMP and cGMP ([Boswell-Smith et al., 2006](#)). Phosphodiesterase-6 (PDE6) is primarily expressed in photoreceptors where it plays a critical role in phototransduction, it consists of the catalytic α and β subunits, an inhibitory γ subunit and a non-catalytic δ subunit ([Zhang et al., 2015](#)). Phosphodiesterase-6 delta subunit (PDE6 δ ; also known as PDE δ , PrBP/ δ and PDE6D) is a 17kDa prenyl binding and solubilizing factor for Ras and Rab GTPases ([Chandra et al., 2011](#)). Originally first identified as a non-catalytic subunit of the photoreceptor PDE6, PDE6D has since been found to be expressed in several other tissue types where it is implicated in the regulation of the dynamic distribution of prenylated proteins ([Dharmaiah et al., 2016](#)). PDE6D consists of a hydrophobic prenyl binding pocket located between two β sheets (**Figure 12**). Consistently, prenylated proteins containing either farnesyl (15 carbon) or geranylgeranyl (20 carbon) units bind to the hydrophobic pocket of PDE6D with the prenylated groups being able to occupy multiple positions inside the hydrophobic pocket of PDE6D ([Dharmaiah et al., 2016](#)). PDE6D interacts with farnesylated and carboxymethylated K-Ras with a binding affinity of $2.3 \pm 0.3 \mu\text{M}$. Absence of the methyl group significantly decreases this affinity (K_d of $82 \pm 9 \mu\text{M}$) emphasizing the importance of both farnesylation and carboxymethylation for the K-Ras/PDE6D interaction ([Dharmaiah et al., 2016](#)). Indeed, an absence of the methyl group resulted in charge repulsion thus diminishing the hydrophobic interactions ([Dharmaiah et al., 2016](#)). Conversely, Chandra et al showed that diminishing the positive charge on the polybasic region of K-Ras by S181 phosphorylating agent bryostatin-1 enhanced the hydrophobic interaction and the ability of PDE6D to effectively solubilize K-Ras ([Chandra et al., 2011](#)).

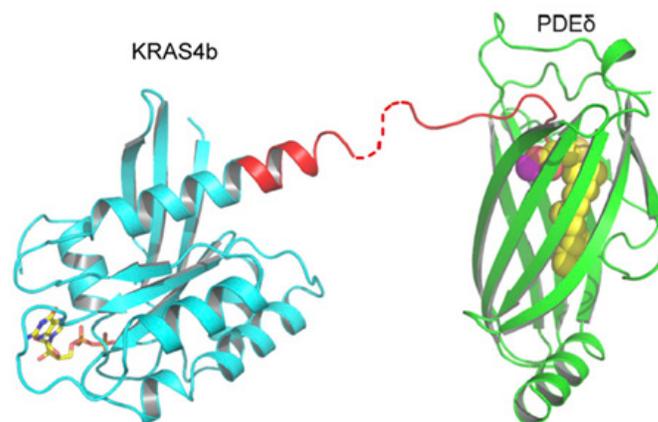

Figure 12. Structure of PDE6D in complex with K-Ras4b. adopted from (Dharmaiah et al., 2016)

Structure illustrates GDP-bound K-Ras4b-Fme in complex with PDE6D. The PDE6D, GTPase domain and HVR of K-Ras4b are shown in green, cyan and red respectively. The farnesyl chain is shown as spheres and colored yellow. The carbon and oxygen atoms of the carboxymethyl group are colored magenta and red respectively whilst GDP is shown as a stick and colored yellow (carbon) and red (oxygen).

1.3.2 The PDE6D/K-Ras interaction and the modulation of K-Ras localization

Lipid modified small GTPases will diffuse and equilibrate randomly across cellular membranes driven by entropy, unless specific transport and delivery systems are available to guide their unloading (Chandra et al., 2011). Indeed, cytoplasmic prenyl binding factors have been proposed to facilitate the cellular trafficking of K/H/ and N-Ras (Chandra et al., 2011). For K-Ras, PDE6D has been identified as a major solubilizing factor able to chaperone K-Ras dynamic distribution to the plasma membrane.

Crystal structure studies on the fully processed K-Ras-PDE6D complex show that the protein-protein interaction may assume two binding modes (Dharmaiah et al., 2016). In the first form, the HVR residues as well as the farnesyl and carboxy-methyl group of K-Ras go deep into the hydrophobic pocket of PDE6D whereas in the second crystal form, most of the residues present in the HVR were not involved in complexation with PDE6D. It has been suggested that the crystal form I is more akin to binding of farnesylated K-Ras to PDE6D whilst the second form is assumed when PDE6D binds with the 20-carbon geranyl-geranylated K-Ras (Dharmaiah et al., 2016).

Although the carboxymethyl and farnesyl groups of K-Ras are critical to the PDE6D-K-Ras interaction, no specific interactions between PDE6D and the G-domain of K-Ras have been observed thus indicating that the nucleotide binding state of K-Ras is irrelevant to this interaction (Dharmaiah et al., 2016). Because the hydrophobic pocket on PDE6D is too small to accommodate additional lipid chains, PDE6D selectively chaperones K-Ras and other monoprenylated GTPases trafficking over H-Ras and other GTPase with additional lipid chains (Dharmaiah et al., 2016, Schmick et al., 2014, Chandra et al., 2011). This property may explain why PDE6D inhibitors selectively disrupt K-Ras nanoclustering and kill K-Ras driven cancers (Siddiqui et al., 2020).

Mechanistically, mislocalized K-Ras and presumably newly synthesized K-Ras proteins are sequestered from the endomembranes by PDE6D (Schmick et al., 2014). The solubilized K-Ras proteins are then pushed out of the hydrophobic pocket of PDE6D upon GTP- Arl2 mediated allosteric changes on PDE6D at the perinuclear area (Ozdemir et al., 2018). Arl-2, actively facilitates the release of K-Ras on the perinuclear membranes (Ismail et al., 2011). Upon release from PDE6D, the recycling endosomes traps K-Ras into the vesicular transport system mediated trafficking to the plasma membranes (**Figure 13**). Importantly, the Arl2-dependent ejection mechanism of PDE6D cargo is also responsible for the rapid ejection of most small molecule inhibitors developed against PDE6D including deltarasin and deltazinone (Martin-Gago et al., 2017). This explains why despite having compounds with remarkable nanomolar in vitro binding affinity to PDE6D, the cellular anti-cancer effects of the early generation of PDE6D inhibitors are almost a thousand folds lesser (Zimmermann et al., 2013, Papke et al., 2016). Though a new generation of PDE6D inhibitors including deltasonamides and Deltaflexins have been developed that appear to show improved resistance to the Arl2-mediated ejection, efforts towards developing potential clinical candidates for PDE6D inhibition is still in the early stages (Martin-Gago et al., 2017, Siddiqui et al., 2020).

1.3.3 Drug targeting of PDE6D

Recent studies have shown that PDE6D is significantly upregulated in hepatocellular carcinoma and that this overexpression correlated with an enhanced tumor state (Dietrich et al., 2019). It was also found that depletion of PDE6D resulted in a significant reduction in HCC proliferation migration and clonogenicity (Dietrich et al., 2019). In a similar vein another study assessing the expression patterns of PDE6 subunits in breast cancer cell lines found PDE6D to be highly expressed across four breast cancer cell lines irrespective of their estrogen receptor expression status (Dong et al., 2013). As K-Ras is a client of PDE6D chaperone activity, it is plausible to

suggest that PDE6D may facilitate K-Ras mediated oncogenesis. Indeed, a number of drug discovery efforts assessing novel PDE6D inhibitors have consistently shown that inhibition of the protein in cancers harboring K-Ras mutations such as colorectal, pancreatic and lung is a valid strategy (Klein et al., 2019, Martin-Gago et al., 2017, Papke et al., 2016, Siddiqui et al., 2020, Zimmermann et al., 2013). Taken together, current evidence supports PDE6D as a relevant protein in cancer progression either independently or in conjunction with its K-Ras modulating cellular functions.

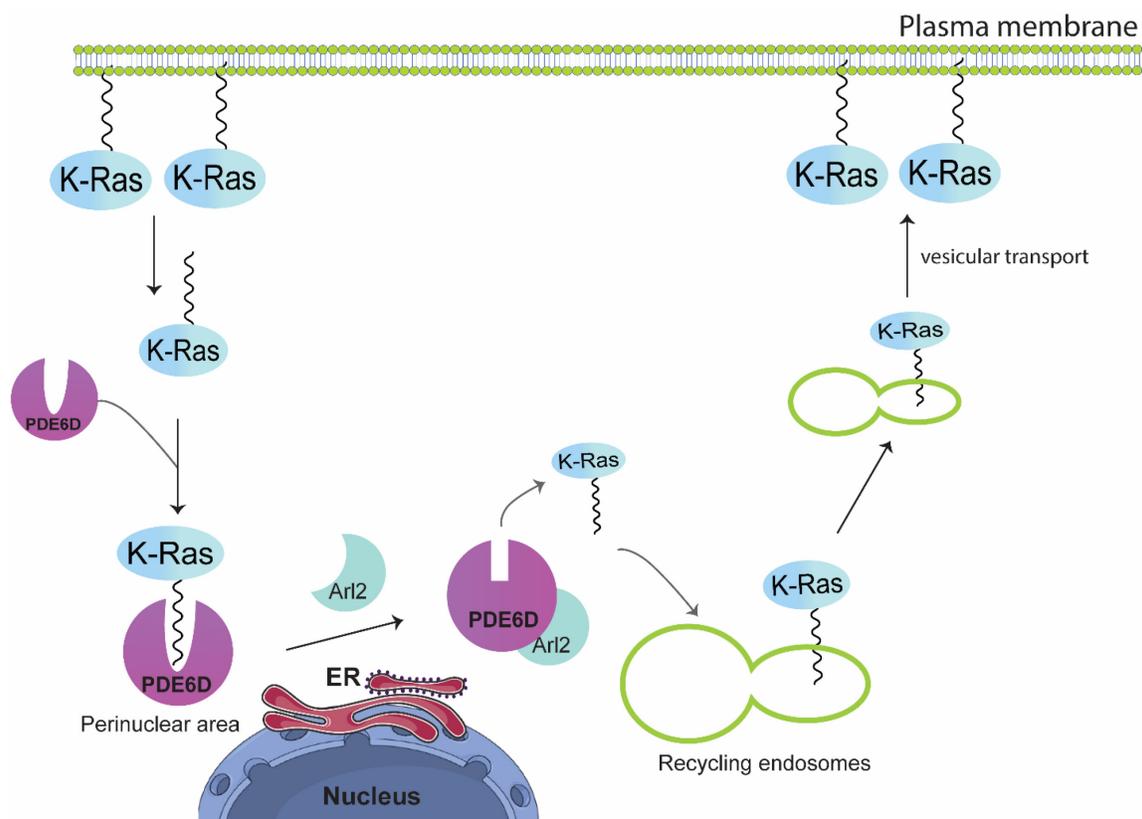

Figure 13. Mechanistic model of PDE6D trafficking of K-Ras.

Mislocalized and potentially newly synthesized K-Ras proteins are sequestered from the endomembranes by PDE6D. The K-Ras cargo on PDE6D is ejected through the action of Arl2-GTP in the perinuclear area. Once released, the recycling endosomes trap K-Ras and facilitates its membrane localization via the vesicular transport system.

The first PDE6D inhibitor is named Deltarasin (Zimmermann et al., 2013). Deltarasin is a benzimidazole small molecule inhibitor that binds at low nanomolar concentrations ($K_D = 38$ nM) to the prenyl binding hydrophobic pocket of PDE6D (Zimmermann et al., 2013). This compound was found to cause the mislocalization of K-Ras and blocked the growth of K-Ras driven pancreatic cancer in cells as well as in pancreatic cancer xenograft models (Zimmermann et al.,

2013). However, this compound in addition to exhibiting unspecific toxicity also suffers from the Arl2-mediated ejection mechanism previously discussed. A second generation compound deltazinone was developed (Papke et al., 2016). This compound showed improved in vitro affinity for PDE6D ($K_D = 8 \text{ nM}$) and better selectivity for inhibiting K-Ras driven cancer cell proliferation. However, this compound in addition to being ejected by Arl2 was found to be unsuitable for animal studies as it is rapidly metabolized in mice (Papke et al., 2016). To counter the challenges of bioavailability and Arl2 ejection, third generation PDE6D inhibitors deltasonamide 1 and 2 with picomolar in vitro affinity to PDE6D (K_D deltasonamide 1 = $203 \pm 31 \text{ pM}$; K_D deltasonamide 2 = $385 \pm 52 \text{ pM}$) were developed (Martin-Gago et al., 2017). The improved affinity of the deltasonamides was rationalized by their ability to form up to 7 hydrogen bonds with the hydrophobic pocket for PDE6D (Martin-Gago et al., 2017). Importantly, these compounds showed improved cellular activity in addition to selectively inhibiting the growth of K-ras dependent cell lines. Deltasonamides also showed an improved resistance to Arl2 unloading primarily due to the improved binding affinity to the hydrophobic pocket potentiated by its ability to form up to 7 hydrogen bonds with critical amino acid residues within the pocket (Martin-Gago et al., 2017). A different strategy involving the innovative proteolysis targeting chimera system (PROTACs) has been recently adopted in PDE6D drug development. PROTACs are hetero bifunctional molecules that links a protein of interest (POI) ligand to an E3 ubiquitin ligase thus facilitating the proteosomal degradation of the POI via the ubiquitin proteasome system (UPS) (Sun et al., 2019). The Waldmann group recently developed a PDE6D PROTAC using the deltasonamides as the PDE6D ligand due to their picomolar affinity to PDE6D. Indeed, the PROTACs selectively depleted PDE6D protein levels but surprising revealed a previously unknown role of PDE6D in the regulation of lipid metabolism (Winzker et al., 2020). They specifically showed that the PDE6D inhibitor PROTAC increased the sterol regulatory binding protein (SREBP)-mediated gene expression of lipid metabolism enzymes which was accompanied by an increase in the level of cholesterol biosynthesis precursors (Winzker et al., 2020). Another study that recently assessed potentially unidentified targets of the clinical multikinase inhibitor sorafenib using the PROTAC approach showed that PDE6D is indeed a target of sorafenib as evidenced by the proteosomal degradation of PDE6D in several cell lines treated with the sorafenib based PROTAC (Yang Li, 2020).

1.4 The K-Ras trafficking chaperone calmodulin

1.4.1 Molecular structure and biology of CaM

CaM is a 16.7 KDa, acidic, ubiquitously expressed, master calcium regulator protein that has been implicated in many cellular processes including cell cycle regulation, Muscular contraction, apoptosis as well as cell proliferation (Tidow and Nissen, 2013). Structurally, CaM possess two fairly symmetrical globular lobes separated by a flexible linker (the N and C lobes). Each lobe contains a pair of EF hands each capable of coordinating a calcium ion (4 Ca²⁺ in total) (Figure 14) (Tidow and Nissen, 2013). Each lobe of CaM can independently bind protein targets either in the calcium bound holo-enzyme and/or calcium free apo-enzyme states (Marshall et al., 2015). The C lobe of CaM exhibits a 3-fold higher binding affinity for calcium and this binding of calcium to CaM induces conformational changes that results in the exposure of a methionine rich hydrophobic pocket on each lobe (Yang et al., 2003, Crivici and Ikura, 1995, Cox, 1988). Whilst CaM traditionally binds to helical, basic peptides harboring two hydrophobic side chains spaced by 2 to 18 residues, a number of non-canonical binding partners possessing a mono-lipidated polybasic N- or C terminus have been identified (Tidow and Nissen, 2013, Grant et al., 2020c). CaM's exceptional protein target binding spectrum is exemplified by its ability to bind well over 400 proteins in humans and mice including proteins such as cell surface receptors, kinases, phosphatases, ion channels, small GTPases etc. (Tebar et al., 2020). This property is enabled by the protein's flexibility conferred by its linker region and the fact that CaM's N and C lobe are able to assume open and closed conformational cycles depending on their calcium-bound states (Chou et al., 2001).

The protein sequence of CaM is identical across all vertebrate species making it one of the most highly conserved proteins known (Toutenhoofd and Strehler, 2000). Importantly, this ubiquitously expressed protein is also encoded for by 3 identical non-allelic genes which creates a highly debated conundrum of genetic redundancy (Toutenhoofd and Strehler, 2000). It has been suggested that this seemingly redundant evolutionary event is meant to ensure the availability of "back-up" copies of CaM. However, Toutenhoofd and Strehler hypothesize that the three gene copies may not be redundant copies but rather suggest that vertebrate cells exploit this multigene nature of CaM to regulate the local, spatial and temporary availability of CaM (Toutenhoofd and Strehler, 2000). CaM is able to undergo a number of post-translation modifications including carboxymethylation, phosphorylation at Thr26, Thr29, Thr79, Ser81, Tyr138, Tyr99, Ser101 and Thr117 as well as tri-methylation at Lys115 (Murtaugh et al., 1980, Benaim and Villalobo, 2002,

Magnani et al., 2010). Indeed, these differential PTMs may facilitate its selective interaction with various proteins spatio-temporarily.

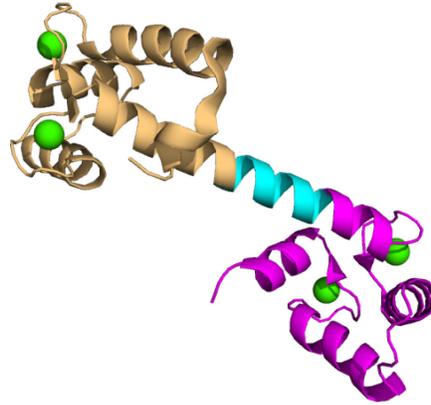

Figure 14. Protein Structure of CaM.

3D structure of fully loaded calmodulin in complex with four (4) calcium ions (green balls). CaM is a 148 amino acid long protein consisting of two fairly symmetrical N and C lobes joined by a flexible linker region. The 3D structure was rendered with Pymol (PDB 4DJC).

1.4.2 The Role of CaM in the cell cycle and MAPK signaling

Cell proliferation is amongst the many processes regulated by $\text{Ca}^{2+}/\text{CaM}$ (Kahl and Means, 2003). Actively dividing eukaryotic cells undergo proliferation through a series of stages termed the “cell cycle”. The cell cycle consist primarily of; an initial gap phase (G1), a synthesis phase (S) where DNA is replicated, a second gap phase (G2) and a mitosis phase (M) in which cytoplasmic and chromosomal components are divided into two daughter cells (Otto and Sicinski, 2017). The transition through the phases of the cell cycle is tightly regulated by a number of proteins including the cyclin-dependent serine/threonine kinases (CDKs) (Otto and Sicinski, 2017). CaM is required for normal cell cycle progression notably during; re-entry from quiescence (G0), upon mitogenic stimulation, during the G1/S boundary, during G2/M transition, M phase progression as well as during mitotic exit (Kahl and Means, 2003). Studies have shown that CaM binds to the carboxyl terminal of cyclin-dependent kinase inhibitor 1 ($\text{p}21^{\text{CIP1}}$) (Rodriguez-Vilarrupla et al., 2005). $\text{p}21^{\text{CIP1}}$ in addition to its CDK inhibitory role, acts as a bridge molecule in the CDK4/ cyclin D1 complex (LaBaer et al., 1997). Similarly, CaM has been shown to bind directly to cyclin E (Choi et al., 2006). Consistently, it was this significant body of evidence implicating CaM in the cell cycle that inspired initial interests in targeting CaM in cancer several decades ago.

The epidermal growth factor receptor, a major upstream regulator of the Ras/MAPK signaling pathway is a CaM binding protein (Li and Villalobo, 2002, Tebar et al., 2002). Murine EGFR was isolated by Ca²⁺ dependent CaM-affinity chromatography (Li and Villalobo, 2002, Tebar et al., 2002). Similarly, a Ca²⁺ dependent direct binding of CaM to the juxtamembrane region of the receptor (amino acids 645-660) was shown (Martin-Nieto and Villalobo, 1998). Taken together, these studies established a relevance of CaM interaction with a critical upstream components of Ras signaling. CaM was first shown to bind exclusively to K-Ras among the major Ras isoforms in affinity chromatography studies by the Neus Agell Group (Villalonga et al., 2001). Their study suggested that the interaction between K-Ras and CaM was direct and that this interaction modulates the Ras-MAPK signaling pathway (Villalonga et al., 2001). Likewise, they showed that binding of CaM to K-Ras prevents the phosphorylation of Ser181 by PKC in vivo (Alvarez-Moya et al., 2010). Their data suggested that the inability of K-Ras to be phosphorylated causes a markedly decreased ability of K-Ras to stimulate proliferation in saturated serum conditions (Alvarez-Moya et al., 2010). Furthermore, they demonstrated that the phosphorylation of K-Ras also regulates oncogenic K-Ras function such as focus formation capacity, apoptosis resistance upon Adriamycin treatment as well as tumor cell mobility (Alvarez-Moya et al., 2010). However, recent studies on the role of Ser181 phosphorylation in modulating the K-Ras/CaM interaction appears to sharply contrast this view (Wang et al., 2015b). It was suggested that PKC mediated phosphorylation of Ser181 of K-Ras compromises its binding to CaM and suppresses tumorigenicity (Wang et al., 2015b).

1.4.3 The K-Ras4b/CaM interaction and the modulation of K-Ras localization

Of the 4 Ras isoforms, CaM interacts exclusively with K-Ras4b (Villalonga et al., 2001). Although some contradictions exist regarding the specific details of the K-Ras/CaM interaction, a significant and robust body of evidence indicates that the interaction is calcium dependent, nucleotide independent, farnesylation dependent, and G-domain independent (Grant et al., 2020b, Sperlich et al., 2016, Agamasu et al., 2019, Jang et al., 2019, Villalonga et al., 2001).

Structurally, the hydrophobic pockets of the N and C lobes of Ca²⁺ CaM can potentially bind to farnesylated K-Ras in a 1:2 stoichiometry involving 1 CaM and 2 K-Ras molecules (Agamasu et al., 2019). The C-lobe was shown to exhibit a 10 fold higher affinity for K-Ras (C lobe K_D = 0.4 μM; N lobe K_D = 4.0 μM) (Agamasu et al., 2019). Similarly, another group showed using chemical

The K-Ras trafficking chaperone calmodulin

shift perturbations NMR that farnesylation was absolutely required for specific interactions of K-Ras with CaM (Grant et al., 2020b). Crystal structure of CaM in complex with farnesylated and carboxymethylated K-Ras reveals that the methionine rich hydrophobic pocket on CaM sequesters the farnesyl moiety (Grant et al., 2020b). Importantly, electrostatic interactions between the acidic flexible linker of CaM and the polybasic HVR of K-Ras (KSKTKC) have also been suggested as a significant contributor to this interaction (Wu et al., 2011, Grant et al., 2020b, Agamasu et al., 2019). In addition to C185 farnesylation, Ser181 of K-Ras has also been identified as a critical residue for the interaction with calmodulin (Alvarez-Moya et al., 2010, Wang et al., 2015b). Binding of CaM to K-Ras prevents the phosphorylation of Ser181 and the phosphorylation of this residue by PKC has been shown to compromise the K-Ras/CaM interaction (Alvarez-Moya et al., 2010, Wang et al., 2015b).

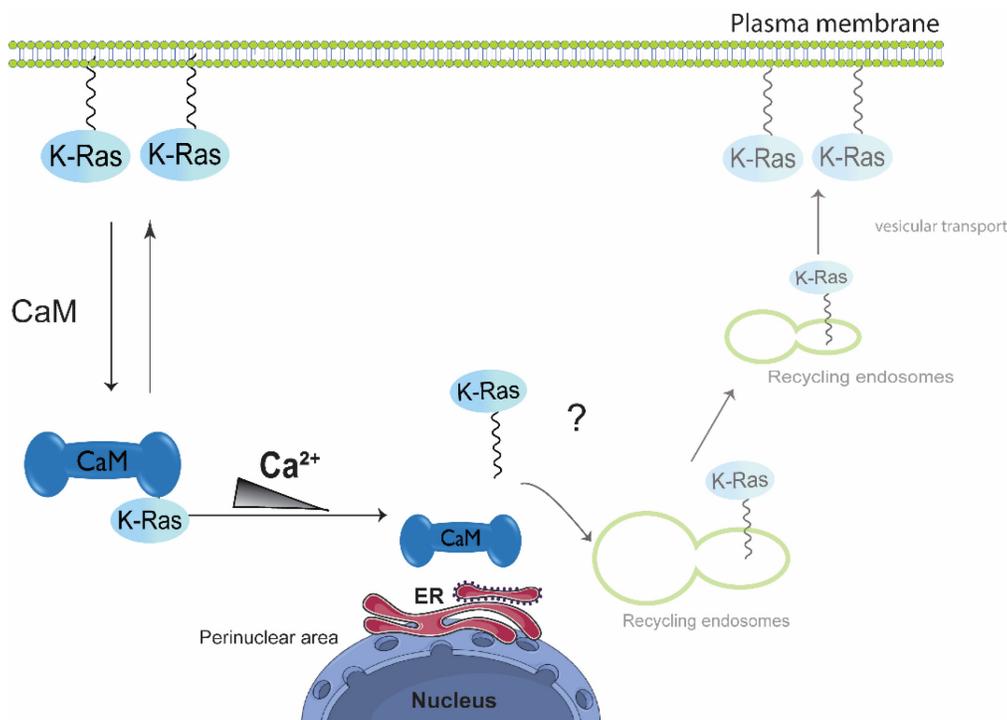

Figure 15. Proposed mechanism of K-Ras trafficking by CaM.

Ca²⁺/CaM facilitates the reversible translocation of K-Ras from the plasma membrane into the cytoplasmic space. A calcium dependent release mechanism of K-Ras is initiated at subcellular regions with lower Ca²⁺ gradients. Released K-Ras may then be trapped by the recycling endosomes in areas near the recycling endosome. In such a system, the RE subsequently aids plasma membrane enrichment of K-Ras via vesicular transportation.

An earlier study into the effects of CaM interaction on K-Ras localization showed that Ca²⁺/CaM facilitates the reversible translocation of K-Ras from the plasma membrane in hippocampal neuronal cells (Fivaz and Meyer, 2005). Recent evidence have suggested that CaM is able to

extract K-Ras from the PM (Agamasu et al., 2019, Sperlich et al., 2016). Indeed, in vitro studies using nanodiscs, membrane mimetics and anionic monolayers indicate that CaM sufficiently outcompetes these artificial membranes for the K-Ras farnesyl moiety (Agamasu et al., 2019, Sperlich et al., 2016). Similarly, cellular experiments have shown that CaM is able to sequester K-Ras from the plasma membrane (Grant et al., 2020b, Sidhu et al., 2003). Since both CaM and the PM bind to the same structural elements on K-Ras, the interaction to either partner is mutually exclusive. Using a chimeric CaM-K-Ras fusion protein construct (CaMeRas) in a live cell FRET experimental setup, Grant et al demonstrated a Ca^{2+} and farnesylation dependent reversible K-Ras membrane detachment process in which the CaMeRas-WT construct was internalized upon Ca^{2+} stimulation whereas, the Ca^{2+} deficient CaMeRas mutant failed to be internalized (Grant et al., 2020b).

Furthermore, since Ca^{2+} ion concentrations at different subcellular compartments undergo a dynamic flux through activation and inactivation of Ca^{2+} channels, stores and pumps, K-Ras may be released by CaM at low Ca^{2+} gradient regions within the subcellular space (**Figure 15**), thus potentially allowing for other K-Ras trafficking chaperones like PDE6D to ferry K-Ras unto the relevant structures for subsequent localization to the membrane (Sperlich et al., 2016, Capiod, 2013, Berchtold and Villalobo, 2014). In such a scenario, CaM and PDE6D act as cooperating units in modulating K-Ras membrane association and signaling. Such cooperativity may become interesting in the context of synergistic targeting of Ras driven cancers.

Co-localization of interacting proteins in various subcellular structures may be indicative of functional activity within such structures. In addition to its plasma membrane localization, K-Ras has been found on the ER, Golgi and Mitochondria (Bivona et al., 2006, Prior and Hancock, 2012). Interestingly, Ca^{2+} /CaM is also reported to localize on and even regulate protein transport to the Mitochondria, ER, Golgi as well as the Nucleus (Berchtold and Villalobo, 2014, Aich and Shaha, 2013). Therefore, it is reasonable to speculate that K-Ras and CaM may interact to modulate other non-canonical cellular functions outside of the PM.

1.4.4 Role of CaM in cancer development

Elevated levels of Ca^{2+} /CaM has been reported in multiple human and animal tumors (Liu et al., 1996, Berchtold and Villalobo, 2014). CaM has been reported to promote cell proliferation, migration, autophagy and apoptosis in cancer (Berchtold and Villalobo, 2014). Consistently, early studies using the CaM antagonists trifluoperazine and W-7 in combination with tamoxifen, an estrogen receptor inhibitor induced apoptosis in breast cancer cell lines indicating the relevance of CaM for cancer growth and survival (Frankfurt et al., 1995). Similarly, CaM has been implicated in the promotion of tumor-associated angiogenesis, a process whereby tumor cells grow new

blood vessels to enhance their oxygen supply (Berchtold and Villalobo, 2014). Hypoxic stress occurs in poorly vasculated tumor microenvironments thereby causing an increase in cytosolic Ca^{2+} and the formation of $\text{Ca}^{2+}/\text{CaM}$ complexes, this promotes the transcriptional activity of the hypoxia inducible factor (HIF-1) thus increasing the expression of the vascular endothelial growth factor (VEGF) which promotes angiogenesis (Shen et al., 2007). Furthermore, the interaction between K-Ras and CaM has been found to influence both MAPK and PI3K/AKT signaling output (Nussinov et al., 2015). Indeed, recent evidence have implicated this K-Ras/CaM interaction as a promoter of cancer cell stemness by suppressing non-canonical frizzled 8-mediated Wnt signaling (Wang et al., 2015b).

Taken together, the evidence above points to an important role of CaM in the development of the malignant phenotype. Indeed, it is clear that the relevance of CaM for the maintenance of normal cell division and proliferation coupled with its ability to interact with many proteins, some of which are oncogenes (e.g K-Ras) implicates CaM in the development of cancer.

1.4.5 CaM inhibitors

A conditional tetracyclin-dependent CaM knockout system in chicken lymphoma DT40 cells developed by the Berchtold group in which two CaM genes are deleted and the third gene is replaced with an artificially regulated transgene showed that CaM is critical for survival of vertebrate cells (Panina et al., 2012). They also showed that overexpression of ectopic wild-type CaM or CaM with one fully active Ca^{2+} binding domain restored cell viability (Panina et al., 2012). However, because of the evidence implicating $\text{Ca}^{2+}/\text{CaM}$ in various malignancies, small molecules against this protein have been sort for several years now. Indeed, many inhibitors with distinct chemical properties have been assessed for their anti-CaM activity in various tumors.

CaM inhibitors including CaM antagonist calmidazolium (CMZ), naphtalenesulfonamides such as the highly soluble and cell penetrating W-7, W-5 and W-13 as well as the clinically approved phenothiazine antipsychotic trifluoperazine have all been shown to reversibly inhibit CaM (Sunagawa et al., 1999, Hidaka et al., 1981, Sengupta et al., 2007, Weiss et al., 1980, Huang et al., 2019). Similarly, natural product E6 berbamine, the wasp venom peptide polistes mastoparan, the small molecule CGS-9343B as well as artemisinin and tehranolide have all been shown to inhibit CaM in several cancer cell lines (Hu et al., 1992, Mou et al., 2019, Barnette et al., 1983, Hilchie et al., 2016, Neuhaus and Reber, 1992, Noori and Hassan, 2014, Black et al., 1989). A group of anti-fungal azole derived compounds including miconazole and econazole have also been shown to inhibit CaM activity (Hegemann et al., 1993). Interestingly, a recent study on miconazole showed that the compound induced an increase in CaM gene expression suggesting

that CaM inhibition by the compound leads to a compensatory protein overexpression in aquatic species (Breitholtz et al., 2020).

1.4.6 CaM covalent inhibitors

Despite a generally cautious attitude towards covalent inhibitor development by the pharmaceutical industry, several covalent compounds have been approved for the treatment of a number of clinical conditions including clopidogrel (a covalent modifier of P2Y purinergic receptor 12), lansoprazole (a H⁺/K⁺ ATPase inhibitor) and esomeprazole (also a H⁺/K⁺ ATPase inhibitor prescribed for heartburns), these inhibitors featured in the top 10 selling drugs in the US in 2009 (Singh et al., 2011). In oncology, key covalent inhibitors include inhibitors of Aromatase, thymidylate synthase and ribonucleotide reductase (Singh et al., 2011). Many covalent inhibitors act via cysteine residue modification due to the high intrinsic reactivity of this amino acid and structure-guided targeting of non-catalytic cysteine is a widely adopted strategy in drug discovery (Cuesta and Taunton, 2019). Lysine residue targeting covalent inhibitors have been mostly unexplored even though a large set of potentially targetable lysines have been identified (Cuesta and Taunton, 2019).

Ophiobolin A (OphA) is a lysine reactive covalent inhibitor of CaM (Hait et al., 1987, Leung et al., 1984). This potent anti-fungal sesterpenoid natural product was shown to covalently modify lysine residue 75, 77 and 148 on CaM and block K-Ras mutated cancer spheroid growth (Leung et al., 1984, Najumudeen et al., 2016). OphA can react with CaM at a 2:1 ratio, similar to covalent phenothiazine derivative trifluoromethyl phenothiazine (POS-TP) which also react with Lys148 (Faust et al., 1987, Leung et al., 1984). In addition to its potency against CaM, OphA appears to show activity against several other targets including phosphatidylethanolamine (Chidley et al., 2016). The phenothiazine antipsychotic fluphenazine-N-2-chloroethane (fluphenazine mustard) is also known to irreversibly modify CaM (SI Table 1) (Hwang et al., 2009).

Due to the critical role CaM plays in many cellular processes, development of inhibitors against this target has been met with extreme caution (Villalobo and Berchtold, 2020). However, the availability of clinically approved compounds that bind to CaM such as the phenothiazine antipsychotics indicates that perhaps, CaM inhibition may be tolerated. Recent studies indicate a stemness context specific collaboration of CaM and K-Ras (Wang et al., 2015b). Disruption of this interaction through PKC mediated S181 phosphorylation as well as the direct inhibition of CaM by OphA demonstrated anti-cancer activity (Wang et al., 2015b, Najumudeen et al., 2016). Taken together, the growing body of evidence suggests that targeting CaM in K-Ras driven cancers may offer a new window of opportunity for drug development (Najumudeen et al., 2016, Wang et al., 2015b, Saito et al., 2017).

1.5 Targeting oncogenic Ras signaling

With the exception of the recently approved K-RasG12C covalent inhibitor sotorasib (Lumakras), K-Ras remains a largely undrugged oncogenic target (Amgen, 2021). The paucity of drug binding pockets on the surface of these proteins has made the prospect of direct inhibition a huge challenge that has only been partly resolved a few years ago (Ostrem et al., 2013). Consequently, indirect targeting of Ras through both upstream and downstream effector inhibition have been the most widely explored and extensively discussed below (Figure 16) (Moore et al., 2020).

1.5.1 Inhibition of signaling upstream of Ras

For Ras to be activated, several upstream processes are required including; (1) an intact signal relay system from growth factors through GEFs and GAPs as well as (2) processes that facilitate Ras localization on the plasma membrane. Because these processes consist of several druggable protein players, they have been extensively exploited in efforts to block Ras oncogenic signaling. The development of clinical EGFR inhibitors (Erlotinib, Afatinib, Osimertinib and Gefitinib) and monoclonal antibodies (Cetuximab, nimotuzumab, necitumumab and Panitumumab) are excellent examples of how blocking upstream Ras signaling can be exploited (Huang et al., 2020, Cai et al., 2020). Also, significant effort has been put into developing inhibitors against the GEF SOS1. Indeed, small molecules that interfered with the SOS-Ras interaction were previously developed but whilst these molecules showed low nanomolar affinity to SOS, assessment in cellular assays yielded poor activity (Sun et al., 2012, Leshchiner et al., 2015, Patgiri et al., 2011). Subsequent efforts led to the development of a small molecule Bay-293 which binds to the CDC25 domain of SOS1 and a region adjacent to switch II on the Ras-SOS1-Ras complex at nanomolar concentrations, Bay-293 was more effective against wild-type K-Ras cancer cells relative to the previous compounds (Hillig et al., 2019). Currently, a clinical trial to assess an SOS1 inhibitor BI 701963 as a single agent and in combinations with the MEK inhibitor trametinib is underway for patients with different types of advanced cancers harboring K-Ras mutations (NCT04111458). SHP2, a non-receptor protein tyrosine phosphatase which acts as a scaffold protein that facilitates Ras nucleotide exchange by binding to GRB2 and SOS1 is also another major target currently being assessed in the context of blocking Ras driven cancers (Moore et al., 2020). In fact, 3 potent allosteric SHP2 inhibitors; RMC 4630, JAB-3068 and TN0155 are undergoing clinical trials (Moore et al., 2020).

1.5.2 Targeting downstream of Ras GTPase signaling

1.5.2.1 Ras/Raf/MEK/ERK pathway inhibition

Activated Ras promotes the recruitment and dimerization of Raf proteins which facilitates the activation of other downstream nodes of the MAPK pathway as previously detailed. To effectively address Ras driven cancers, this pathway needs to be suppressed and many therapeutics have been developed to this effect. Clinical BrafV600-mutant kinase inhibitors vemurafenib and dabrafenib which induce an outward shift of the α C helix in the kinase domain of Raf effectively inhibit Raf monomers (Karoulia et al., 2016). Since BrafV600 mutants signal as monomers, these compounds are effective against the mutated target (Karoulia et al., 2016, Moore et al., 2020). Unfortunately, Ras mutant cancers that signal via dimerized Raf proteins are insensitive to these inhibitors. In fact, these inhibitors even paradoxically activate the MAPK pathway by binding wild-type Raf (Poulikakos et al., 2010). Whilst some details remain unclear, paradoxical ERK activation in the presence of inactive B-Raf depends on enhanced dimerization and transactivation of C-Raf (Poulikakos et al., 2010, Holderfield et al., 2014, Rajakulendran et al., 2009). Consequently, Raf inhibitors which are able to bind both monomeric and dimeric Raf such as belvarafenib, AZ-628, LY3009120 and LXH-254 have been reported to show efficacy against both Ras-mutant and Raf-mutant tumors although some show minimal paradoxical activation (Peng et al., 2015, Vakana et al., 2017, Moore et al., 2020).

Various inhibitors have been developed for MEK, another major downstream effector of the MAPK signaling pathway. The inhibitors cobimetinib, trametinib and binimetinib are clinically approved MEK drugs that are available for treating B-RafV600 mutant melanoma (Hellmann et al., 2019, Hatzivassiliou et al., 2013). Whilst these compounds show benefits against their intended target, they too fail to be efficacious against Ras-mutated cancer (Blumenschein et al., 2015, Moore et al., 2020).

Efforts to develop ERK inhibitors have not yet yielded any clinically approved compounds. However, some promising agents such as GDC-0994 and ulixertinib have been assessed as monotherapeutic agents in various phase I clinical trials (Varga et al., 2020, Sullivan et al., 2018). Similarly, KO-947 and LY-3214996 are currently undergoing clinical assessment for their efficacy in various cancers (Moore et al., 2020).

Targeting oncogenic Ras signaling

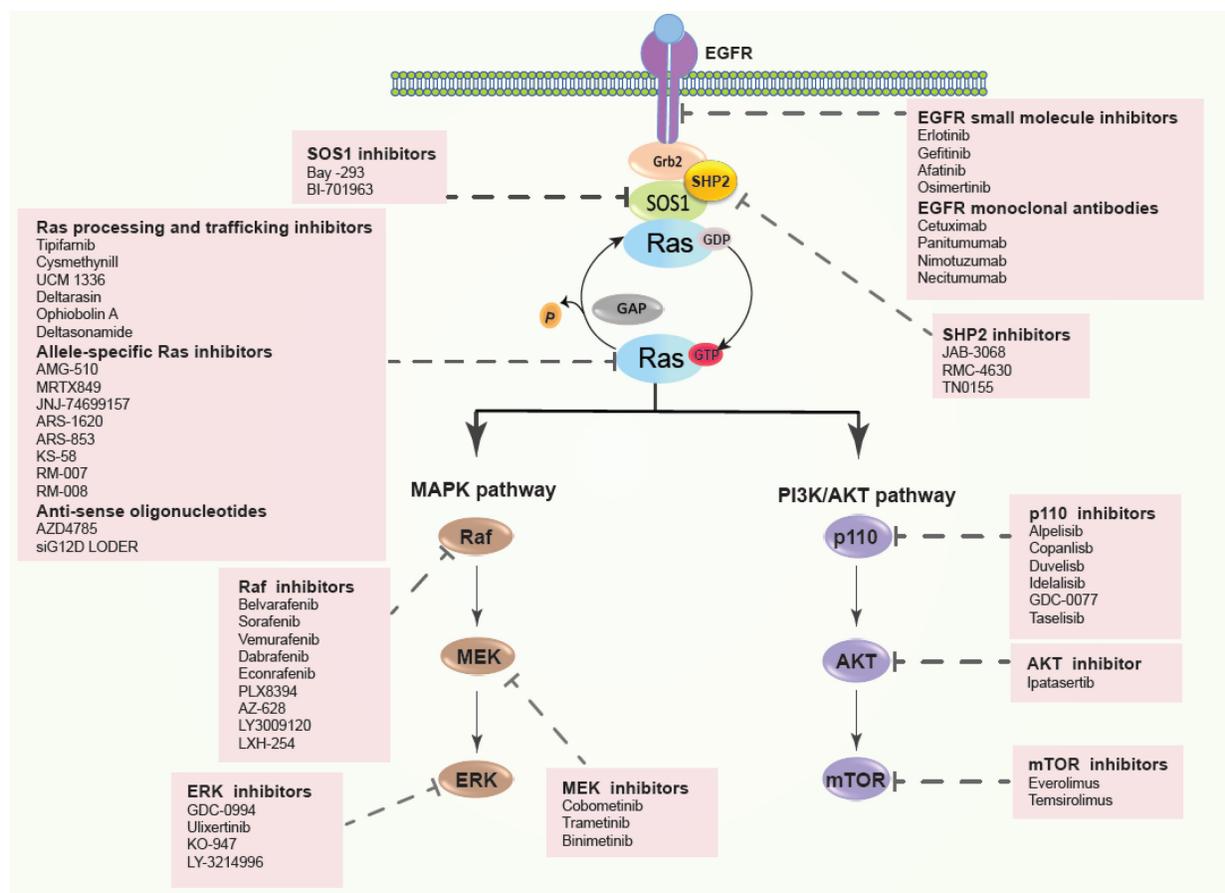

Figure 16. Schematic representation of various Ras targeting approaches. Figure modified from (Moore et al., 2020).

Several therapeutic strategies have been/being developed to reduce the activation of Ras for instance, EGFR small molecule inhibitors and monoclonal antibodies have been developed. Inhibition of SOS and SHP2 is another strategy to decrease GDP-GTP nucleotide exchange. The inhibition of Ras processing and trafficking chaperones is also widely exploited in efforts to mitigate Ras oncogenic signaling. Recent efforts in direct Ras targeting has led to the development of the K-RasG12C specific covalent inhibitors as well as a number of other small molecules in development. Several clinical and experimental drugs have been developed to inhibit Ras downstream effectors of the MAPK and PI3K/AKT signaling pathways including Raf, MEK, ERK, p110, AKT and mTOR.

1.5.2.2 Ras-PI3K/Akt pathway inhibition

Another major alternative downstream pathway modulated by Ras proteins which can be blocked is the PI3K/AKT signaling pathway. Class one PI3K protein p110 α , a ubiquitously expressed isoform and an exclusive client of Ras proteins has been a major subject of research (Fruman et al., 2017). Interestingly though, the clinically approved inhibitor alpelisib, a p110 α inhibitor is not approved for Ras mutated tumors. A combination of multiple redundancies between the MAPK and PI3K pathway continues to facilitate the development of resistance mechanisms (Moore et

al., 2020). Whilst the use of combinatorial and synergistic drug targeting approaches have been employed in many clinical trials, unbearable toxicity issues seem to be widespread with most of these strategies (Wang et al., 2018, Algazi et al., 2019, Moore et al., 2020).

1.5.3 Inhibition of Ras Post-translational processing and trafficking

Another strategy of Ras upstream inhibition involves the blockade of either Ras post-translational processing or the inhibition of key chaperone proteins that facilitate proper localization to the plasma. The development of inhibitors against the post-translational prenylation of Ras proteins include the farnesyl transferase inhibitors (FTIs) and geranylgeranyl transferase inhibitors (GGTIs), inhibitors against the AAX cleavage step i.e Ras-converting enzyme (RCE1) as well as inhibitors of the methylation step of Ras processing; the isoprenylcysteine carboxyl methyltransferase (ICMT) inhibitors is well documented (Moore et al., 2020). The FTI inhibitor tipifarnib shows promise for only patients with H-Ras mutated HNSCC, NSCLC and metastatic urothelial carcinoma due to the fact that K-Ras and N-Ras possessed alternative prenylation mechanism mediated by the GGTases (Gilardi et al., 2020, Zheng et al., 2010, Lee et al., 2020, Whyte et al., 1997). To circumvent the apparent redundancy exhibited by K-Ras and N-Ras mutant cell lines, the RCE1 and ICMT steps which are essential in these cells may be exploited as mutant selective therapeutic approaches. The compounds cismethynil and UCM 1336 have been developed to block ICMT (Wang et al., 2017).

The dynamic distribution of processed K-Ras to the plasma membrane is facilitated by chaperone proteins notably PDE6D and CaM (Chandra et al., 2011, Dharmiah et al., 2016, Grant et al., 2020a, Agamasu et al., 2019). Both chaperones and the various strategies to inhibit them have been extensively reviewed in previous sections of this thesis and constitute the majority of the original contribution of this thesis to Ras biology.

1.5.4 Direct K-Ras inhibitors: K-RasG12C inhibitors and beyond

Kevan Shokat and colleagues pioneered the growing field of Ras covalent inhibitors with their seminal work which developed the first series of irreversible covalent compounds capable of binding to the cysteine mutant K-Ras protein (K-RasG12C) in the GDP-bound form. These compounds trapped the G12C mutant in the GDP form, blocked SOS mediated nucleotide exchange and prevented Raf effector engagement of the mutant (**Figure 17**) (Ostrem et al., 2013). Their crystal structural studies revealed a previously unknown pocket beneath the effector binding switch-II region of K-Ras. Indeed this pocket is available in the other K-Ras G12 mutants but because these other mutants have a lower rate of intrinsic GTPase activity, development of

Targeting oncogenic Ras signaling

covalent inhibitors against their GDP-bound forms might not be nearly as successful relative to G12C-mutated K-Ras (Hunter et al., 2015).

From the Shokat group's first generation of G12C inhibitors, the lead compound was optimized by modifying its linker and hydrophobic binding pocket to generate a more potent and cellular active compound ARS-853 (Patricelli et al., 2016). ARS-853 was further improved by introducing a quinazoline-based series with a fluorophenol hydrophobic binding moiety. This significantly improved pharmacological properties leading to the development of ARS-1620 (Janes et al., 2018).

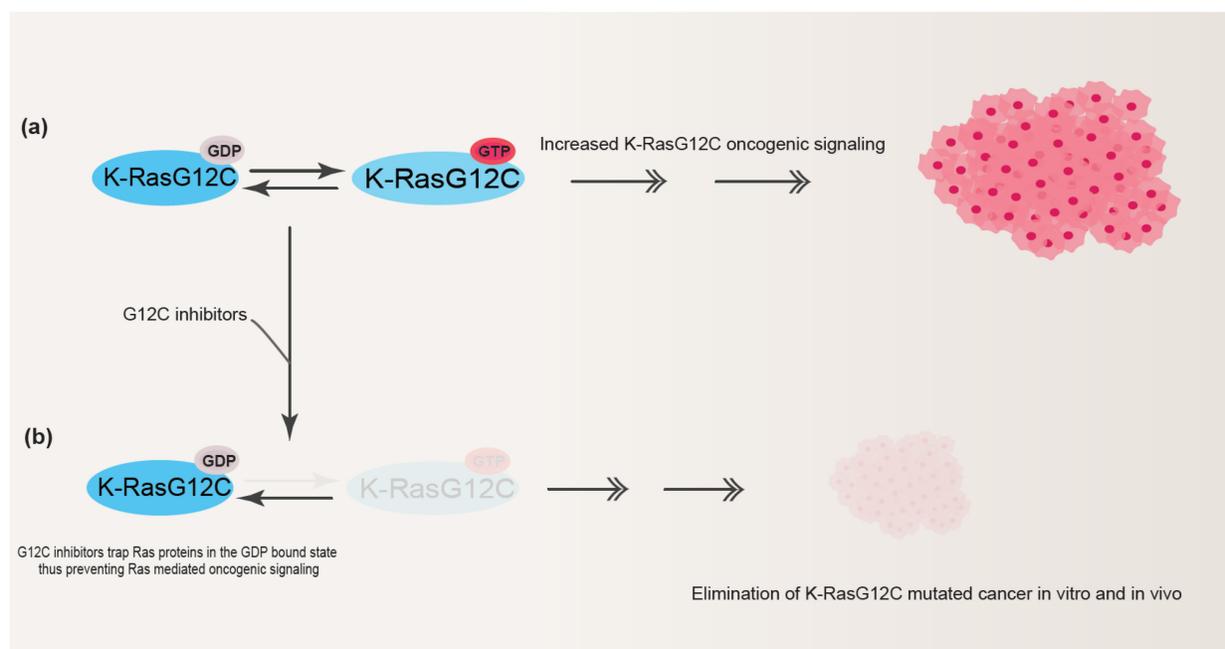

Figure 17. Schematic representation of K-RasG12C inhibition.

Many biopharma companies are developing G12C inhibitors notably Amgen's Sotorasib (AMG-510) which has an additional aromatic ring that improves protein-ligand interactions by exploiting an alternative orientation of His95 in the switch-II pocket (Canon et al., 2019). Sotorasib has been recently granted priority review by the FDA for the treatment of K-RasG12C-mutated locally advanced or metastatic NSCL (Healio, 2021). Approval efforts for sotorasib have made similar progress in Europe and China thus making it potentially the first K-Ras specific inhibitor on track for approval (Biospace, 2021). Mirati's MRTX849 (Adagrasib) is currently also recruiting for a randomized phase 3 clinical trial versus docetaxel in patients with previously treated NSCLC harboring the K-RasG12C mutation (NCT04685135). A third compound ARS-3248 (JNJ-74699157) developed by an exclusive R&D agreement between Wellspring Biosciences, Inc.,

Targeting oncogenic Ras signaling

and Janssen Biotech, completed its phase 1 clinical trials in 2020 in patients with the K-RasG12C mutated NSCLC and CRC, the results have not been announced (NCT04006301).

Since the current K-RasG12C inhibitors require the protein to be bound in the GDP form, mutations that facilitate nucleotide exchange and/or prevent GTPase activity will pose a mechanism of resistance to these compounds (Moore et al., 2020). Indeed a recent study has shown that K-RasG12C mutant cancer cells exhibit heterogeneous response to these inhibitors by producing new K-rasG12C proteins in response to reduced MAPK signaling. Importantly, the new proteins are maintained in the GTP bound state whilst the contribution of drug resistance through EGFR, SHP2 and Aurora Kinase A was implicated (Dunnett-Kane et al., 2021, Xue et al., 2020). Similarly, another recent study showed that clinically acquired resistance to K-RasG12C inhibitors is mediated by a novel switch II pocket mutation (K-RasY96D) (Tanaka et al., 2021). It was identified that this mutation results in the interference of key drug-protein interactions and conferred resistance to G12C inhibitors in engineered and patient derived K-RasG12C cancer models (Tanaka et al., 2021). Coupled with the fact that G12C mutations account for only a small proportion of K-Ras mutated cancers, the need to develop inhibitors that can both target other K-Ras alleles whilst functioning independently of the nucleotide binding state is pertinent. To this end, some molecules have been recently discovered that circumvent the nucleotide dependency, these molecules (RM-007 and RM-008) are able to bind a newly discovered groove adjacent the switch II pocket (Gentile et al., 2017, Moore et al., 2020). Whilst developing inhibitors against other alleles such as the G12V and G12D mutants is currently still in early stages, the recent identification of the peptide KS-58 as a selective inhibitor of K-RasG12D mutated cancer highlight an early promise in this area (Sakamoto et al., 2020). Other approaches including the targeting of all K-Ras alleles with the Pan-K-Ras inhibitor RMC-6236 is also under development.

1.6 Protein phosphatase 2A (PP2A)

1.6.1 Biochemistry and structure of PP2A

Homeostasis of cellular phosphorylation level is achieved by tightly controlled activities of two classes of enzymes- protein kinases, which catalyze transfer of a phosphate group to a specific protein residue, and protein phosphatases, which catalyze the reversed reaction. PP2A belongs to a large family of serine/ threonine protein phosphatases and is classified as phosphoprotein phosphatase (PPP), based on specific sequence motifs in the catalytic site ([Nasa and Kettenbach, 2018](#)). These sites coordinate two bivalent metal ions (Mn^{2+} , Fe^{2+} , Zn^{2+}), which activate water molecule, thereby aiding substrate dephosphorylation ([Zhang et al., 2013](#)). PP2A is one of best established tumor suppressor phosphatases ([Kauko and Westermarck, 2018](#)). Structure of PP2A is very complex ([Xing et al., 2006](#)). In cells, it functions as a heterotrimer ([Sangodkar et al., 2016](#)). Each heterotrimer is built of one unit of the scaffolding (A) (also referred to as PR65), and catalytic (C) subunits, which together comprise the “core enzyme”. Both, A and C subunits, have two different isoforms, α and β , with $A\alpha$ and $C\alpha$ accounting for the majority of each subunit expression in most cells ([Eichhorn et al., 2009](#)). The A subunit contains 15 tandem HEAT (Hungtingtin/ Elongation factor 3/ PP2A A /TOR1) repeats, with each repeat consisting of a tandem helix connected by a loop ([Wlodarchak and Xing, 2016](#)). The core enzyme further complexes with only one member of the regulatory (B) subunits. B subunits are split into four structurally distinct families and are also referred to as B (B55/ PR55), B' (B56/ PR61), B'' (PR48/ PR72/ PR130) and B''' (PR93/ PR110)/ Striatin (**Figure 18**) ([Sangodkar et al., 2016](#)). Whilst these B subunit families exhibit minimal sequence homology across families, members of the same family are structurally similar ([Shi, 2009](#)). Each of the regulatory B subunits has 2-5 different isoforms and splicing variants, adding to combinatorial complexity of PP2A's structural organization. PP2A in fact comprises over 80 distinct holoenzymes ([Sangodkar et al., 2016](#)). The identity of the B subunit determines subcellular localization and substrate specificity of the holoenzyme ([Janssens and Goris, 2001](#)). Activity of PP2A is subject to regulation by post-translational modifications, in particular methylation and phosphorylation of the catalytic subunit. Catalytic subunit can be phosphorylated at Thr304 and Tyr307, with the latter one preventing formation of B55 complexes by inhibiting methylation of Leu309 by Leucine Carboxyl Methyl Transferase 1 (LCMT-1) ([Perrotti and Neviani, 2013](#)).

Protein phosphatase 2A (PP2A)

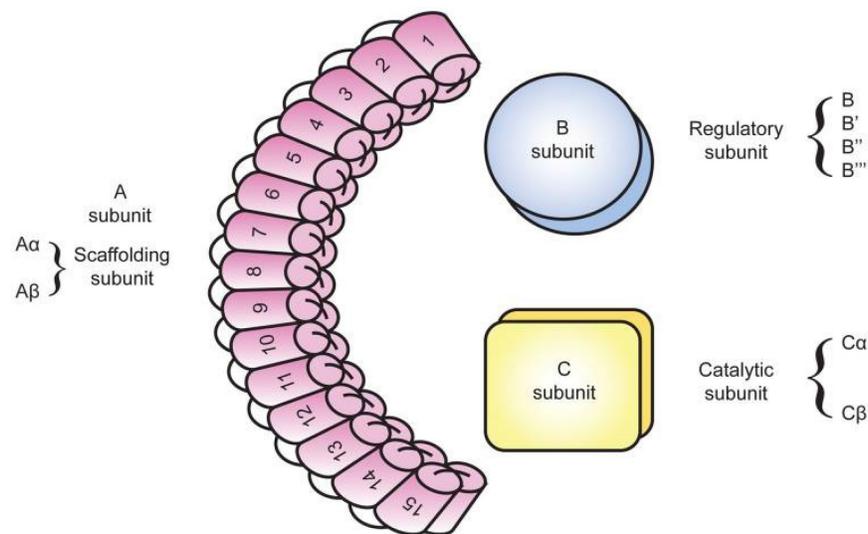

Figure 18. Structural components of the PP2A heterotrimeric complex. Adopted from (Sangodkar et al., 2016)

1.6.2 Role of PP2A in the regulation of Ras signaling pathways

Due to its critical function as a master regulator of cellular phosphorylation events capable of regulating up to 70% of pSer/ pThr sites, PP2A is inadvertently implicated in the control of downstream oncogenic signaling events such as Ras-MAPK pathways and the PI3K/AKT/mTOR pathways (Wlodarchak and Xing, 2016). PP2A has been shown to facilitate the negative regulation of the Ras-MAPK pathway through its binding to the phospho-tyrosine domain of SHC, an important member of the growth factor binding complex of GRB2, SOS and SHC that mediates Ras activations (Ugi et al., 2002). Also, PP2A-B56 have been reported to Downregulate phosphorylation of ERK (Letourneux et al., 2006). Importantly, this PP2A-mediated dephosphorylation is reversed in the presence of the immediate early response gene X-1 (IEX-1) (Letourneux et al., 2006). Similarly, PP2A promotes the dephosphorylation and consequent activation of Sprouty2, a negative regulator of MAPK signaling (Lao et al., 2007). Sprouty2, when phosphorylated, cannot bind to GRB2. However, the dephosphorylation of Sprouty2 by PP2A exposes the GRB2 binding motif on the C-terminus, thus resulting in the inhibition of Ras-MAPK signaling (**Figure 19**) (Lao et al., 2007, Wlodarchak and Xing, 2016).

PP2A is also implicated in the regulation of the PI3K/AKT/mTOR pathway (Kuo et al., 2008). PP2A B56 holoenzyme inhibits AKT by dephosphorylating both T308 and S473 residues (Kuo et al., 2008). Similarly, PP2A has been reported to dephosphorylate S6K, a downstream effector of the mTOR signaling pathway, which promotes cell growth and proliferation (**Figure 19**) (Peterson

[et al., 1999](#)). Furthermore, PP2A has been shown to inhibit the mTOR pathway by dephosphorylating the insulin receptor substrate 1 (IRS1) in the insulin signaling pathway or MAP4K3 in the amino acid pathway ([Yan et al., 2010](#), [Hartley and Cooper, 2002](#)).

1.6.3 Role of PP2A in cancer development

Downregulation of PP2A's activity is not just implicated in oncogenic development, but also in neurodegenerative and intellectual disorders as well as cardiovascular disease ([Mazhar et al., 2019](#)). Cancer remains the primary research focus of PP2A and a number of studies have highlighted the important role of PP2A as a tumor suppressor and indicate that the disruption of the PP2A holoenzyme activity contributes to carcinogenesis ([Perrotti and Neviani, 2013](#)). PP2A inactivation can occur through several mechanisms, including low-frequency somatic mutations of its subunits and methylation and/or phosphorylation of the C-terminal tail of the catalytic subunit ([Perrotti and Neviani, 2013](#)). The major mechanism of PP2A's inactivation across different pathological states is over-expression of its endogenous inhibitory proteins, such as SET (Suvar/Enhancer of zeste/ Trithorax), CIP2A (Cancerous inhibitor of PP2A) or PME-1 (PP2A methylesterase-1), which opposes activity of LCMT-1 ([Reynhout and Janssens, 2019](#)).

Inhibitory proteins are structurally and functionally diverse ([Kauko and Westermarck, 2018](#)). For example, SET binds directly to the catalytic subunit, CIP2A associates with B56 family members and PME-1 demethylates L309 of the catalytic subunit, since L309 is the C-terminal residue important for carboxymethylation and enzyme activation, this PME-1 mediated demethylation leads to expulsion of the metal ions and loss of enzyme activity ([Li et al., 1996](#), [Clark and Ohlmeyer, 2019](#)). Overexpression of PP2A inhibitory proteins such as CIP2A and SET is a prognostic indicator for poor patient survival in cancer ([Cristobal et al., 2012](#), [Cristobal et al., 2015](#)). CIP2A over-expression also drives cancer resistance to kinase or epigenetic inhibitors ([Kauko et al., 2018](#)). Therefore, PP2A reactivation strategies could be applicable in addressing various malignancies.

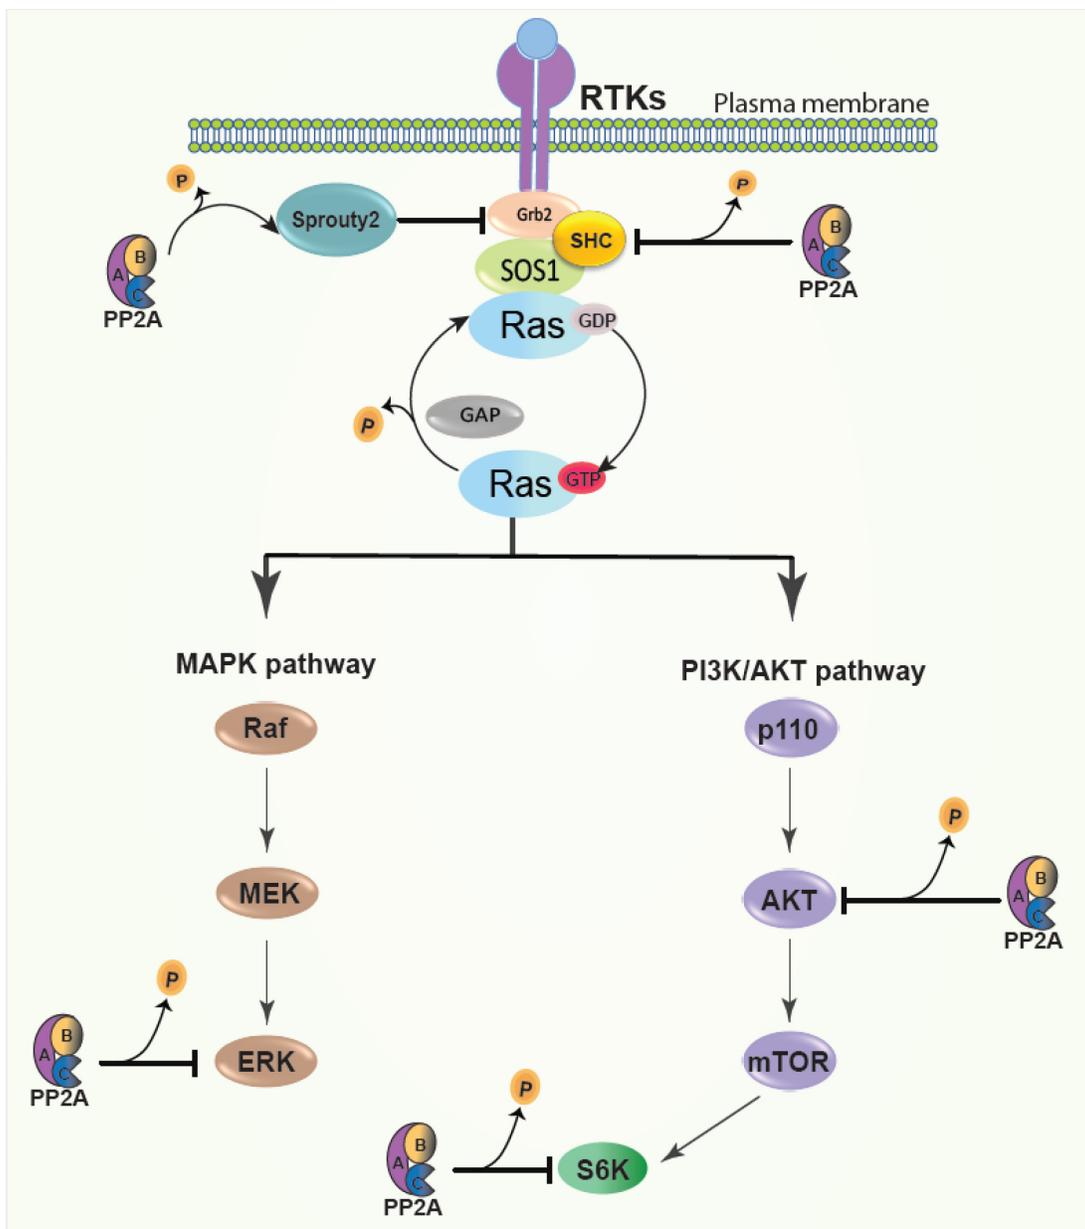

Figure 19. Mechanism of PP2A mediated regulation of Ras downstream signaling

1.6.4 Therapeutic strategies to re-activate PP2A in cancer

Therapeutic efforts aimed at re-activating PP2A in various malignancies are primarily focused on inhibition of the endogenous inhibitors of PP2A and development of small molecules modulators of PP2A activity (Mazhar et al., 2019). For the first strategy, FTY720, the sphingosine analog, has been shown to inhibit SET (Rahman et al., 2016, Neviani et al., 2007). Similarly, SET targeting peptide OP449 is known to reactivate PP2A and was shown to enhance the efficacy of tyrosine kinase inhibitors in myeloid leukemia (Agarwal et al., 2014). Several natural compounds downregulating CIP2A have been reported, for instance ellagic acid contained in red wine was

Protein phosphatase 2A (PP2A)

reported to suppress CIP2A levels in lung cancer although convincing profiling of direct engagement of the target by the compounds is still lacking (Duan et al., 2019). The natural product celastrol induced degradation of CIP2A via CHIP E3 ubiquitin ligase, while its biotinylated derivative was shown to bind to CIP2A in cell lysate (Liu et al., 2014).

PP2A reactivating approach by so-called small molecule activators of PP2A (SMAPs) was pioneered by the Narla group, by re-purposing tricyclic neuroleptics such as phenothiazines, for which potent on and off target effect was known (Kastrinsky et al., 2015). Phenothiazines are antagonists of dopamine D2 receptor with anti-cancer activity (Westermarck and Neel, 2020). Therefore, chemical optimization efforts aimed at improving anti-cancer properties whilst engineering out neuroleptic effects was pursued (Kastrinsky et al., 2015). SMAPs were shown to trigger cell death of K-Ras mutant lung cancer cell lines and to also inhibit tumor growth in a xenograft model (Sangodkar et al., 2017). SMAPs were shown to elicit their anti-cancer effects via PP2A, as presence of a small T antigen from simian virus (SV) 40, a well-established PP2A-binding viral protein, rendered cells resistant to SMAP effect (Sangodkar et al., 2017, Sablina and Hahn, 2008). Recently, crystal structure of the SMAP DT-061 in complex with PP2A-B56 α holoenzyme was resolved (Leonard et al., 2020). DT-061 was shown to act as a “molecular glue” able to stabilize B56 α -containing PP2A heterotrimers. The binding site for the compound was shown to be at the interface of all three PP2A subunits (Leonard et al., 2020). This demonstrated that in spite of high similarity between different subunits of the same B regulatory family, isoform-specific compounds can be designed (Leonard et al., 2020). Furthermore, high-throughput drug screen using 230 kinase inhibitors across two K-Ras mutated lung cancer cell lines showed that PP2A activation status determines response to MEK inhibitors (Kauko et al., 2018). Inhibition of PP2A by siRNA against the A subunit led to an increase in the activation of PI3K/AKT pathway and rendered resistance to MEK and ERK inhibitors (Kauko et al., 2018). Subsequently, activation of PP2A by siRNA against its inhibitory protein CIP2A sensitized cells to these inhibitors, with synergistic effects observed in the co-treatment with SMAPs (Kauko et al., 2018).

AIMS AND OBJECTIVES

2. AIMS AND OBJECTIVES

The development of therapeutics that directly target K-Ras has been largely unsuccessful until recently with the advent of the G12C inhibitors ([Ostrem et al., 2013](#), [Moore et al., 2020](#), [Janes et al., 2018](#)). Still, the majority of K-Ras mutations are not G12C mutated thus not amenable to covalent modification ([Moore et al., 2020](#)). Furthermore, the development of resistance mechanisms against these covalent inhibitors have already been report ([Dunnett-Kane et al., 2021](#), [Xue et al., 2020](#), [Tanaka et al., 2021](#)). Hence, the need to explore alternative approaches including targeting of Ras membrane trafficking chaperones as well as the adoption of multiple synergistic therapeutic strategies that may effectively block Ras mediated signaling output remain relevant.

In this thesis work, I contribute to the development and characterization of novel inhibitors of K-Ras trafficking chaperones PDE6D and CaM respectively Deltaflexins and Calmirasone1. I also show that the synergistic inhibition of CaM and re-activation of the tumor suppressor PP2A with small molecules improved anti-cancer effects on Ras-MAPK dependent cancer cell lines and show that the phenothiazine fluphenazine mustard may act via this mechanism.

Therefore, the 3 main aims of this thesis work are:

1. The development and characterization of novel PDE6D inhibitors with improved resilience to Arl2 ejection and cell penetration.
2. The development and characterization of novel covalent CaM inhibitors with reduced unspecific cytotoxicity and improved K-Ras mediated anti-cancer effects.
3. The evaluation of the potential of phenothiazines to synergistically block CaM and reactivate PP2A in cancer cells.

3.2.2 Overview of the BRET method

Protein-protein interactions are critical for almost all biological processes and a number of techniques have been developed to evaluate these dynamic processes. Bioluminescence resonance energy transfer (BRET) is a form of resonance energy transfer (RET) which relies on the non-radiant energy transfer from the light emitted through the luciferase mediated conversion of a light emitting substrate coelenterazine (James et al., 2006). The first version of the BRET technology developed by Xu et al., used *Renilla luciferase* (Rluc) as the bioluminescent energy donor with its substrate being coelenterazine h and an enhanced yellow fluorescent protein (EYFP) as the acceptor (Xu et al., 1999). However, the technology has since expanded to include a sizable collection of donor-acceptor systems in both live cell and in vivo applications (Dale et al., 2019). Upon co-expression of the protein pairs, the transfer of energy in BRET depend upon the critical factors such as the proximal distance between the BRET pairs, the relative orientation of the BRET pairs as well as the spectral properties of the BRET pairs (**Figure 19**) (El Khamlichi et al., 2019, Bacart et al., 2008).

The distance between the BRET pairs is inversely proportional to the resonance energy transfer. Hence, BRET decreases as the distance between the acceptor and donor pairs increase from 10 to 100 Å (1 to 10 nm) (El Khamlichi et al., 2019, Bacart et al., 2008). Secondly, BRET pairs must have a spectral overlap between the emission spectrum of the donor and the excitation spectrum of the acceptor (El Khamlichi et al., 2019). A third condition for BRET is the maintenance of an aligned spatial orientation of the BRET pairs due to the dipole-dipole nature of the resonance energy transfer process (**Figure 19**) (El Khamlichi et al., 2019, Bacart et al., 2008).

BRET differs from foster resonance energy transfer (FRET) in a number of ways. For instance, unlike FRET which must be excited by monochromatic light for signal generation, BRET does not require external illumination. Hence, the quantification of energy transfer is easier in BRET than in FRET (Boute et al., 2002). in BRET, the relative expression of the biosensors can be independently quantified by measuring the luminescence of the donor and fluorescence of the acceptor (Boute et al., 2002). Another challenge of FRET is the photo-bleaching of the donor fluorophore due to repeated exposure to light, this results in the overall loss of signal over time (Boute et al., 2002).

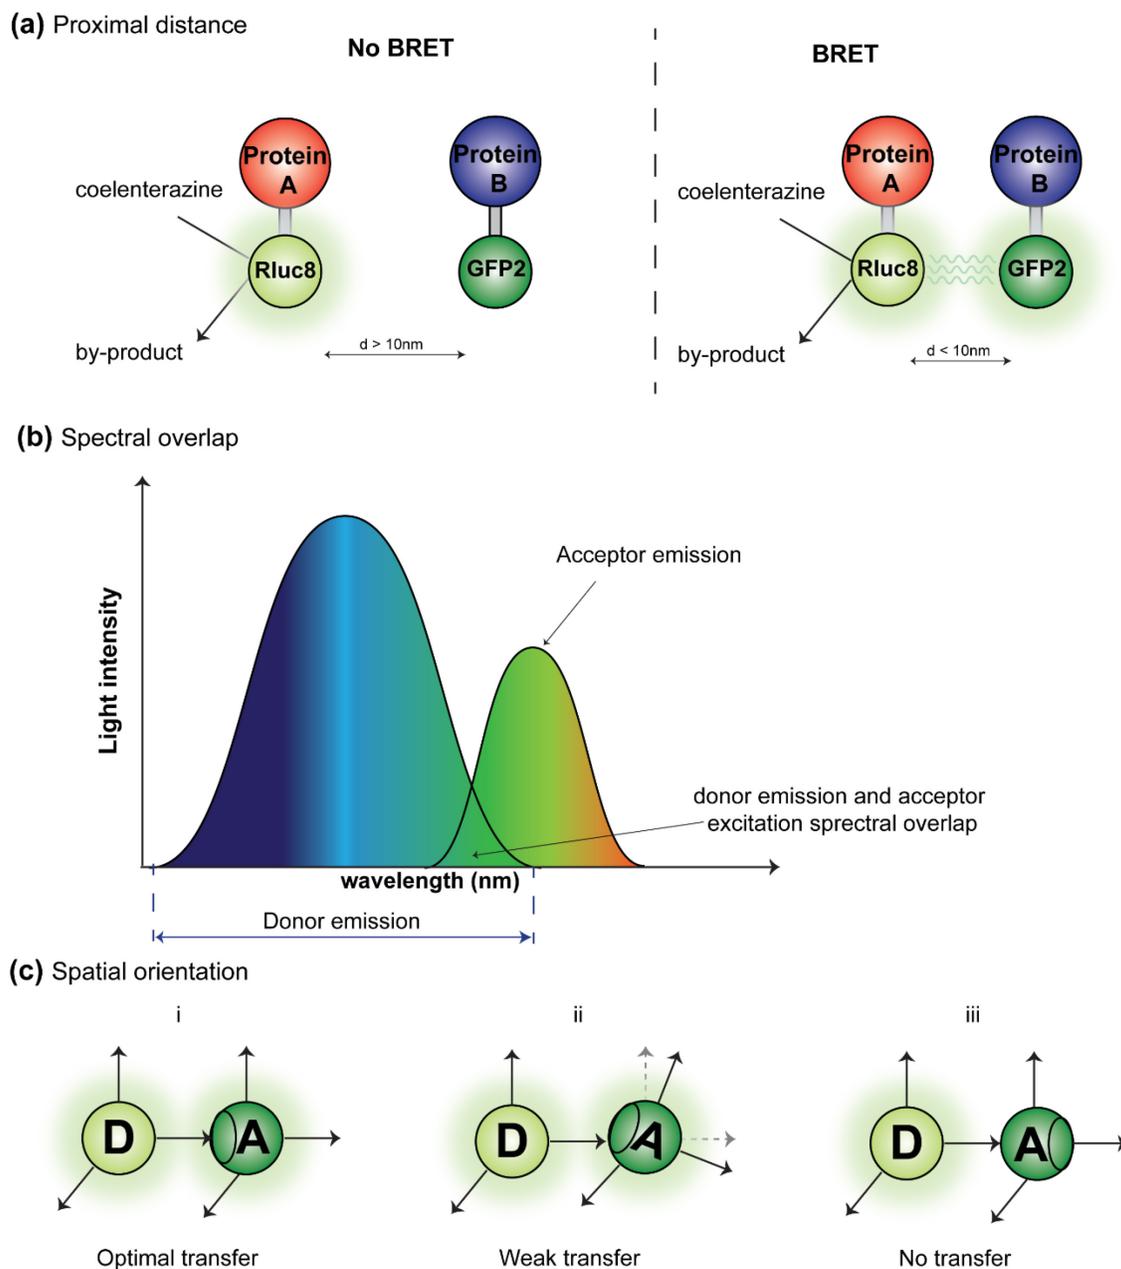

Figure 19. Schematic illustration of the conditions for BRET

Schematic illustrations of critical conditions for BRET based energy transfer. **(a)** Donor luminophore (Rluc8) must be within a 10nm proximal distance to the acceptor fluorophore (GFP2). **(b)** The donor emission spectral wavelength must overlap with the acceptor excitation wavelength for BRET to occur. **(c)** Donor and acceptor must maintain an aligned spatial orientation for BRET to occur due to the dipole-dipole nature of the resonance energy transfer process.

Materials and methods

Multiple BRET systems including BRET1, BRET2, eBRET2, BRET3 and quantum dots (QDs) BRET have been developed (Bacart et al., 2008). Each system is compatible with different donor-acceptors pairs and diverse experimental applications including, live cell imaging, in vivo imaging, drug screening etc. (Bacart et al., 2008). The BRET 1 system uses coelenterazine h (benzyl-coelenterazine) as a substrate for the luciferase. The maximum emission of Rluc was observed at 480nm and this wavelength is particularly suited for the excitation of a yellow fluorescent protein (YFP) variant named enhanced YFP (EYFP) at 530nm. This system have been applied for the screening of compounds as well as for cell imaging experiments (Bacart et al., 2008). The BRET2 system which improves upon BRET1 uses DeepBlueC™ (Coelenterazine 400a), a chemical derivative of coelenterazine h which shifts the emission maximum of Rluc to 395nm. The optimal acceptors for this system are GFP2 and GFP10 with excitation and emission maxima of 400 and 510nm respectively. BRET2 offers the advantage of having a better separation of the spectra of the donor and acceptor emission peaks (Bacart et al., 2008). Consequently, BRET2 is superior to BRET1 particularly in compound screening applications where low signal to background ratios are desired (Bacart et al., 2008). However, DeepBlueC™ exhibits a 300-fold lower capacity for light emission thus requiring the overexpression of a conjugated luciferase protein (Hamdan et al., 2006). To overcome this limitation, an enhance version of Rluc named Rluc8 (containing 8 amino acid substitutions) (Pfleger and Eidne, 2006). This new eBRET2 system achieves a 32-fold increase in quantum yield when DeepBlueC™, and leads to a 5.5-fold improvement in the BRET signal in addition to the strong spectral resolution of the standard BRET2 system (Pfleger and Eidne, 2006, Bacart et al., 2008). eBRET2 is widely used in compound screening and drug discovery projects, live cell imaging and in vivo experiments due to the advantages pointed out (De et al., 2007, Xu et al., 2007, Massoud et al., 2007, Bacart et al., 2008). The application of BRET in Ras protein-protein interaction studies have recently led to the identification of Ras-Raf interface inhibitors (Bery et al., 2018, Bery and Rabbitts, 2019). Indeed, these new tools will allow for the identification of small molecules capable of disrupting Ras isoform specific interactions. In this thesis, we have generated Ras isoform biosensors as well as biosensors for the assessment of the K-Ras/CaM interaction based on the eBRET2 system. We validated their suitability for the screening of small molecules and found the technique to be robust and high-throughput amenable.

3.2.3 BRET assay

BRET assays were extensively used in this thesis for the evaluation of protein-protein interactions and the effects of inhibitors on the stated interactions. The BRET experiments were essentially performed as described by others (Bery et al., 2018, Lavoie et al., 2013). About 100,000 to 150,000 HEK293-EBNA cells were seeded per well of a 12-well plate in 1 mL of DMEM containing 10% FBS and 2 mM L-glutamine and were grown for 24 h. Next day, Rluc8-tagged donor and GFP2-tagged acceptor constructs were transfected into cells using jetPRIME transfection reagent. Each well was transfected with about 1 µg of plasmid DNA using 3 µL of jetPRIME reagent. For BRET donor saturation titration experiments, the concentration of donor plasmid (25 ng) was kept constant and the concentration of acceptor plasmid was increased from 0 to 500 ng for Ras-G12V BRET pairs and 0 to 1000 ng for K-Ras/ CaM BRET pairs. The empty pcDNA3.1(-) plasmid was used to top-up the total DNA load per transfection. After 24 h of transfection, cells were treated with compounds or vehicle control (DMSO 0.2% v/v in growth medium) at the specified concentration for 24 h or the stipulated time period in case of the time-course experiments.

The cells from one well of a 12-well plate were collected, washed, and re-plated in PBS on flat bottom, white 96-well plates as four technical replicates containing 90 µL of cell suspension per well. Then fluorescence intensity followed by BRET readings were carried out on Clariostar plate reader at 25 °C. The fluorescence intensity (RFU) of GFP2 was measured with excitation at 405 ± 10 nm and emission 515 ± 10 nm; it is proportional to the acceptor concentration [acceptor]. BRET readings were taken well by well by adding 10 µL of 100 µM coelenterazine 400a, the Rluc8 substrate to each well using the injector present in the plate reader. Luminescence emission intensities were simultaneously recorded at 410 ± 40 nm (RLU, proportional to [donor]) and 515 ± 15 nm (BRET signal).

The raw BRET ratio was calculated as the BRET signal measured at 515 nm divided by emission signal measured at 410 nm (RLU). The BRET ratio was obtained by subtracting the raw BRET ratio by a background BRET signal measured for cells expressing only the donor (Bacart et al., 2008) as indicated in the formula below,

$$BRET\ ratio = \frac{\lambda_{em\ 515\ nm}_{(donor+acceptor)}}{\lambda_{em\ 410\ nm}_{(donor+acceptor)}} - \frac{\lambda_{em\ 515\ nm}_{(donor\ only)}}{\lambda_{em\ 410\ nm}_{(donor\ only)}}$$

With *donor+acceptor* denoting cells transfected with the BRET pair and *donor only* being cells expressing only the donor.

Materials and methods

The expression of acceptor relative to donor ($[\text{acceptor}]/[\text{donor}]$) was determined as, $\text{relative expression} = \frac{RFU}{RLU}$

For BRET donor saturation titration experiments, the BRET ratio was plotted against the ratio of acceptor to donor plasmid amounts (A/D plasmid ratio) that were transfected or the relative expression. The A/D plasmid ratio at which the BRET ratio changes most linearly with the relative expression was determined for each BRET sensor and then used for testing compound treatments. The BRET ratio vs relative expression data were fit into a binding saturation equation in the Prism (GraphPad) software to obtain the $BRET_{\text{max}}$ and $BRET_{50}$ using the equation, $y = \frac{BRET_{\text{max}} \times x}{BRET_{50} + x}$, where x is the relative expression and y is the BRET ratio. The $BRET_{\text{max}}$ represents the maximum saturation BRET signal and depends on structural parameters (distance, orientation) of the BRET complex. $BRET_{50}$ corresponds to the ratio of acceptor construct over donor construct required to attain 50% of the maximum BRET signal and is a measure of the effective relative affinity between the interacting BRET pair (Marullo and Bouvier, 2007).

3.2.4 Drug sensitivity score (DSS) analysis

The quantitative profiling of the drug sensitivities of the various cell lines used in this thesis was evaluated with the drug sensitivity score (DSS) analysis. DSS values are essentially normalized area under the curve (AUC) measures of dose-response inhibition data which provide a more robust representation of drug activity compared to the classic EC_{50} and IC_{50} curves (Yadav et al., 2014). Drug response data files (in Excel) ready for online analysis were prepared according to the example file obtained from the DSS pipeline website, called Breeze (<https://breeze.fimm.fi/>) (Potdar et al., 2020). Either raw fluorescence intensity measurements or normalized % inhibition data (for BRET assay analysis) were uploaded.

The output file provides several drug sensitivity measures including EC_{50} and AUC. We plotted the DSS_3 value (Yadav et al., 2014), which was calculated as

$$DSS_3 = DSS_2 \frac{x_2 - x_1}{C_{\text{max}} - C_{\text{min}}}$$

Where DSS_2 is given by the equation $DSS_2 = \frac{DSS_1}{\log a}$

and DSS_1 is given by the equation $DSS_1 = \frac{AUC - t(x_2 - x_1)}{(100 - t)(C_{\text{max}} - C_{\text{min}})}$

DSS_3 was employed to emphasize drugs that obtain their response area over a relatively wide dose window, as compared to drugs that show increased response only at the higher end of the concentration range. After logistic fitting of the dose-response inhibition data, the area under the curve (AUC) was determined as exact solution. A 10% minimal activity threshold (t) was set. The

Materials and methods

maximum (C_{max}) and minimum (C_{min}) concentrations were used for screening of the inhibitors, with $C_{max} = x_2$ and x_1 concentration with minimal activity t . The parameter a is the value of the top asymptote, which is different from 100% inhibition as obtained from 100 μ M benzethonium chloride treatment.

3.2.5 Synergism experiments and Bliss scoring

To access the synergistic potential of our compounds, we performed a full dose response analysis of one agent (calmidazolium) and maintained a fixed concentration of the other inhibitor (DT-061, either 1 or 2 μ M). The drug response profiles obtained for the various combinations in the cell lines were then compared against the profiles of each single agent using the SynergyFinder platform. SynergyFinder (<https://synergyfinder.fimm.fi>) is a stand-alone web-application for interactive analysis and visualization of drug combination screening data (lanevski et al., 2020). We employed the Bliss model (Bliss, 1939). Which generates the multiplicative effects of single agents as if they acted independently in scoring our pairwise combinations

$$S_{BLISS} = E_{A,B,\dots,N} - (E_A + E_B + \dots + E_N - E_A E_b - E_A E_N - E_B E_N - \dots - E_A E_B \dots E_N).$$

Here, E_A, E_B, \dots, E_N are the measured responses of the single drugs, while b are the doses of the single drugs required to produce the combination effect $E_{A,B,\dots,N}$.

3.2.6 Western blotting

MiaPaCa-2 cells were lysed cell lysis buffer (50 mM Tris, 150 mM NaCl, 0.1% SDS, 1% triton, 1% NP40 and a Roche tablet for 10 ml lysis buffer volume) and incubated on ice for 30 min. Cell lysates were mixed with Laemmli buffer with 0.1% bromophenol blue heated for 5 min at 95°C and resolved on a 12% home-made gel. Proteins were subsequently transferred to a membrane using the Trans®-Blot® Turbo® Transfer system (BIO-RAD). The blotted membranes were incubated for 1 h in blocking buffer (5% BSA in Tris-buffered saline (TBS)-T (Tween 0.1%)) and treated with primary antibodies for pERK 1:400 (Santa cruz, sc-81503), ERK 1:1000 (Cell Signaling, 9102) A mouse antibody against GAPDH 1:2000 (Sigma, G8795) was used for housekeeping gene control. After overnight incubation, the membrane was washed 3× 5 min in TBS-T buffer the following day and then treated with the corresponding anti-rabbit and anti-mouse secondary antibodies (1:10000 dilutions). The proteins were detected using a LI-COR ODYSSEY CLx system (Westburg). The level of proteins was densitometrically quantified from western blot membranes using ImageLab software (BIO-RAD).

4.1.1 Manuscript 1: Summary

Ras mutations are present in about 19% of all solid malignancies worldwide ([Prior et al., 2020](#)). Despite the recent successes with covalent direct K-RasG12C inhibitors, a majority of K-Ras mutated malignancies remain undrugged. PDE6D is a trafficking chaperone of K-Ras and other prenylated proteins capable of modulating the dynamic localization of K-Ras to the plasma membrane where it is required for signaling ([Chandra et al., 2011](#)). Small molecules developed against PDE6D have shown promise in in vitro and in vivo studies ([Papke et al., 2016](#), [Zimmermann et al., 2013](#), [Martin-Gago et al., 2017](#)). However, the PDE6D cargo ejection process mediated by Arl2 also results in the undesirable removal of these compounds from PDE6D ([Martin-Gago et al., 2017](#)). By increasing the hydrogen-bonding capabilities of these compounds, some improvements were made but the lingering challenge of ejection still persists ([Martin-Gago et al., 2017](#)).

In this study, our goal was to develop PDE6D inhibitors with improved resilience to the Arl2-mediated unloading whilst improving cell penetration and overall anti-cancer activity. To this end, we proffered an alternative design strategy for PDE6D inhibitors. We engineered a “chemical spring” consisting of a flexible hexyl linker into these new inhibitors to minimize prenyl pocket ejection and attached a cell penetrating group to improve cellular uptake and cellular potency. A small collection of compounds was generated and assessed in assays such as surface plasmon resonance (SPR) and fluorescence polarization for evaluating compound binding to PDE6D. Fluorescence life-time imaging based FRET (FLIM-FRET) was used for the evaluation of isoform specific inhibitory properties of the compounds whilst target engagement of the compounds was

evaluated in a K-Ras/PDE6D FRET assay. The 3D spheroid assay was utilized for evaluating their effects on K-Ras driven stemness characteristics.

Collectively, our results identified **Deltaflexin 1** and **Deltaflexin 2** as selective disruptors of K-Ras but not H-Ras membrane organization. These compounds also showed anti-cancer effects on K-Ras driven cancer cell lines of lung, breast and colon origins. Importantly, our compounds showed selectivity for inhibiting K-Ras driven stemness characteristics as compared to the B-Raf-V600E mutant melanoma cell line. Although this generation of our compounds showed low overall cellular potency to proceed as viable drug candidates, the novel design principle proves to be useful in minimizing Arl2-mediated ejection and will form the basis for our next generation Deltaflexins drug development efforts.

4.1.2 Manuscript 1: Personal contributions of Sunday Okutachi

- Designed, performed and analysed the sphere formation and cell proliferation experiments
- Designed and generated figure 4E
- Analysed and generated the ATARiS gene dependency profiling of the cell lines (SI figure 3G)
- Involved in discussions and drafting of corresponding data contribution

The personal contributions of all authors to the manuscript are listed in the *Authors' contributions* Section at the end of the corresponding manuscript.

Supporting Information

ABSTRACT: The trafficking chaperone PDE6D (also referred to as PDE δ) has been nominated as a surrogate target for K-Ras4B (hereafter K-Ras). Arl2-assisted unloading of K-Ras from PDE6D in the perinuclear area is significant for correct K-Ras localization and therefore activity. However, the unloading mechanism also leads to the undesired ejection of PDE6D inhibitors. To counteract ejection, others have recently optimized inhibitors for picomolar affinities; however, cell penetration generally seems to remain an issue. To increase resilience against ejection, we engineered a “chemical spring” into prenyl-binding pocket inhibitors of PDE6D. Furthermore, cell penetration was improved by attaching a cell-penetration group, allowing us to arrive at micromolar in cellulo potencies in the first generation. Our model compounds, Deltaflexin-1 and -2, selectively disrupt K-Ras, but not H-Ras membrane organization. This selectivity profile is reflected in the antiproliferative activity on colorectal and breast cancer cells, as well as the ability to block stemness traits of lung and breast cancer cells. While our current model compounds still have a low in vitro potency, we expect that our modular and simple inhibitor redesign could significantly advance the development of pharmacologically more potent compounds against PDE6D and related targets, such as UNC119 in the future.

INTRODUCTION

The oncogene Ras is one of the best-established cancer targets without an approved inhibitor. Ras drug development efforts in the 1990s were thwarted by the failure of farnesyltransferase inhibitors (FTI) in clinical trials.¹ At that time, it was underappreciated that the highly mutated K-Ras and N-Ras can be alternatively prenylated by geranylgeranyltransferase I, reinstating Ras plasma membrane localization and thus activity, even in the presence of FTIs.²

Recently, there has been a resurgence in Ras drug development, with both direct and indirect targeting approaches.³ The Shokat group has pioneered direct, covalent inhibitors that target a switch II pocket in GDP-bound K-RasG12C.⁴ Efficacy of these compounds relies on the intrinsic GTPase activity of that mutant and trapping of an inhibitor-bound inactive state.⁵ Therefore, inhibitor efficacy can be increased by enriching the cellular pool of GDP-bound K-RasG12C, such as through inhibition of upstream receptor tyrosine kinases (e.g., EGFR, FGFR1, AXL) or Ras/Sos1 inhibitors, such as BAY-293.⁶

Switch II pocket inhibitors have rapidly evolved⁷ and are now in clinical trials.⁸ Thus, it is for the first time possible to assess the effect of selectively targeting a driver oncogene. While lung cancer patient data are encouraging, the durable responses and adaptive immunity that is seen in animal models are striking and may indicate the significance of K-Ras inhibition for curing cancer.

Given that other mutant K-Ras alleles are not targeted by these covalent inhibitors, different K-Ras inhibition approaches are still needed. Therefore, other noncovalent Ras binders with inhibitory potential remain interesting. They were typically discovered by computational approaches, such as the Kober compounds or pyrazolopyrimidine allosteric compounds, which block Ras-effector interaction and have micromolar cellular potencies.^{9,10}

(A) Design of Deltaflexin compounds, where in the first generation a generic heterocycle “top” was linked via a flexible hexyl “spring” to the protected phosphodiester “bottom”. (B) SPR data of Deltarasin and compounds **15** (Deltaflexin-1), **14** and **17**; $n = 3$. N-terminal avi-tagged K-RasFMe was captured on a neutravidin sensor chip and the inhibitory activity of compounds for the PDE6D/avi-K-RasFMe interaction was measured. (C) Dose–response curve of Deltarasin and compounds **15** (Deltaflexin-1), **14** and **17** from the SPR data. (D) Docked structure of Deltaflexin-1 into the crystal structure of PDE6D in the open (cyan, PDB code 4JV8) and Arl2-GTP-bound, closed state (green, PDB code 1KSJ). Right shows details of PDE6D (open) residues in proximity of docked Deltaflexin-1.

The indirect target PDE6D is a trafficking chaperone of farnesylated proteins, which may suggest that its inhibition affects the same clients as inhibition of farnesyltransferase. However, PDE6D has a different client profile than farnesyl-

transferase, as it cannot facilitate intracellular diffusion of proteins that are also palmitoylated.^{11,12} Moreover, PDE6D has the potential to accommodate geranyl-geranylated clients.¹² Thus, PDE6D inhibition selectively affects K-Ras4B (hereafter

K-Ras) trafficking but has much less effect on trafficking of dual-palmitoylated H-Ras.^{11,13}

In order to relay signaling, K-Ras needs to be localized predominantly to the plasma membrane. This requires energy-dependent vesicular transport of K-Ras to the plasma membrane from the recycling endosome, where it is collected after PDE6D-assisted diffusion from internal cellular membranes.^{11,13} Unloading of K-Ras from PDE6D in the perinuclear compartment requires the binding of GTP-Arl2 to PDE6D, which results in an allosteric conformational change in PDE6D that effectively releases its cargo.¹⁴ Unfortunately, this ejection mechanism also applies to the first two generations of PDE6D inhibitors Deltarasin¹⁵ and Deltazinone,¹⁶ developed by the Waldmann group. Only their third generation of PDE6D inhibitors, the Deltasonamides, can largely withstand Arl2-mediated ejection, as they were highly optimized for sub-nanomolar affinity. However, these compounds have a low partitioning coefficient, suggesting low cell penetration.¹⁷ Unfortunately, this theme of micromolar cellular potency, despite nanomolar affinity to the target in vitro, also continues with more recent PDE6D inhibitors that emerged through substantial fragment-based discovery and structure-based virtual screening efforts by the Xiong and Sheng groups.¹⁸

In order to advance PDE6D inhibitor development, it may therefore be necessary to change the overall concept, as the discovery of various chemotypes with high in vitro affinity has been well demonstrated. We here present Deltaflexins, which have only micromolar in vitro, yet also micromolar in cellulo potencies. We have overcome the approximately 1000-fold in vitro to in cellulo potency gap, by employing an innovative compound engineering approach.

RESULTS AND DISCUSSION

Generic Design of PDE6D Inhibitors with a Flexible Hexyl-Linker and Cleavable Cell Penetration Group. In order to improve the resilience of inhibitors against Arl2-mediated ejection from the PDE6D prenyl-binding pocket, a flexible hexyl linker that was envisaged to act like a buffering spring, was attached to a moiety that would provide major contacts to the “top” of the pocket. The design was completed by a simple phosphodiester “bottom” moiety, which was protected with a previously developed cell penetration group that was tunable for pharmacological stability.^{19,20} In our first-generation model compound, Deltaflexin-1 (**15**), the generic, heterocyclic coumarin was chosen as “top”-moiety, as it would allow for H-bonding and π -stacking (Figure 1A). In addition, a panel of seven control compounds was synthesized that allowed us to assess the contribution of each of the design elements (Figures 1A, S1A).

In order to validate the inhibitory activity of the compounds on the PDE6D/K-Ras interaction, we established a surface plasmon resonance (SPR) assay. Farnesylated and carboxymethylated K-Ras (K-RasFMe) were captured on the sensor chip surface via an avi-tag, and the binding of PDE6D was measured (K_d PDE6D/avi-K-RasFMe = $3.6 \pm 0.1 \mu\text{M}$) (Figure S1B, Table 1). Deltaflexin-1 (**15**) bound with a surprisingly good, low micromolar K_d that was only 2.6-fold higher than what we determined for Deltarasin (Figure 1B,C, Table 1). This was encouraging given that this was the first generation of compounds. Importantly, the control compound **17** with a “stiff”, methyl cyclohexylmethyl linker had essentially the same affinity to PDE6D as compound **15** and therefore represented an excellent control for testing the significance of the flexible hexyl

Table 1. Inhibitory Activities of Deltaflexins and Control Compounds on Binding of PDE6D to avi-K-RasFMe as Determined by SPR

compound	inhibition of PDE6D/avi-K-RasFMe	
	IC ₅₀ ± SEM/ μM	K_d ± SEM/ μM
Deltarasin	1.9 ± 0.1	1.4 ± 0.1
15 (Deltaflexin-1)	4.87 ± 0.03	3.61 ± 0.02
19	inconclusive

23 (Deltaflexin-2)	3.94 ± 0.03	2.92 ± 0.02

linker later on in cells (Figure 1C, Table 1). The relatively hydrophobic **14**, which lacked the cell-penetration bottom-moiety exhibited a reduced binding activity (Figure 1C, Table 1). Surprisingly, compound **19** the phosphorylated (charged) derivative of **14** showed an increase in the SPR response, suggesting stabilization of the PDE6D/avi-K-RasFMe complex. Direct target binding data were corroborated by a previously published fluorescence anisotropy (FA) assay, which detects displacement of a fluorescently labeled, farnesylated peptide derived from the PDE6D client Rheb (F-Rheb)¹⁴ (Figure S1C, Table S1).

Computational docking of Deltaflexin-1 into the PDE6D crystal structure suggested that similar to the Deltasonamide derivatives, the phosphotriester bottom moiety of Deltaflexin-1 forms hydrogen bonds with Arg61 and Gln78, at the base of the PDE6D pocket (Figures 1D, S1D,E).^{16,17} In addition, the top-moiety contacted Glu88, Ala112, and Met117. Therefore, three out of the seven contacts that were also engaged by the most optimized deltasonamide derivative (compound **8**¹⁷) were utilized by Deltaflexin-1, consistent with the overall similar positioning of the compound (Figure S1E). A comparison of Deltaflexin-1 docked into PDE6D in the open and closed (Arl2-bound) state illustrates that the potential steric clash between the protected phosphodiester at the bottom of the pocket and Arg61 would likewise persist (Figure 1D). However, the presence of the adjacent flexible hexyl linker may enable the protected phosphodiester bottom moiety of Deltaflexin-1 to evade this clash.

Deltaflexin-1 Disrupts K-Ras/PDE6D Interaction and K-Ras Membrane Organization in Cells. Next, we tested for on-target activity in cells, using a FRET-assay, which directly detects the interaction between K-RasG12V and PDE6D. Deltaflexin-1 significantly reduced the FRET to a level comparable to that of Deltarasin (Figure 2A). This activity was also seen with three derivatives that employed different chemical coupling between top and linker moieties, suggesting a notable degree of flexibility for compound synthesis (Figure S2A). By contrast, the control compound, **17**, with a “stiff” methyl-cyclohexylmethyl linker moiety, lacked in cellulo activity (Figure 2A), despite identical in vitro activity (Table 1). Likewise, **14** and **19** without the cell-penetration bottom-moiety did not block the interaction (Figure 2A). In support of the middle moiety requiring a specific length, shortening of the methylene-linker to four carbons abrogated the inhibitory activity in **20** (Figure 2A). Similar results were obtained using the previously described FRET-pair of PDE6D and another client, the farnesylated Ras-like GTPase Rheb (Figure S2B).¹¹

PDE6D inhibition is expected to suppress K-Ras localization and activity more than H-Ras.¹³ We therefore employed an

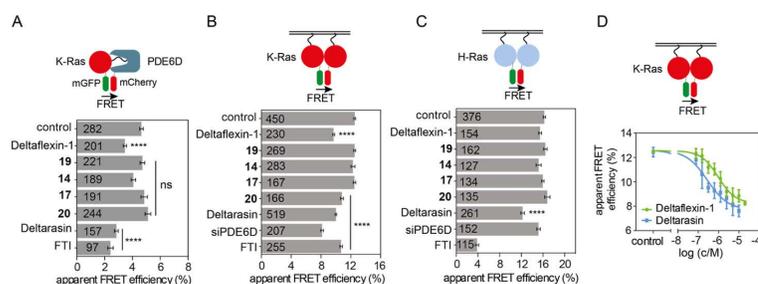

Figure 2. Deltafloxin-1 inhibits K-Ras/PDE6D interaction and selectively disrupts K-Ras membrane organization (A) PDE6D/K-Ras interaction by FLIM-FRET. HEK cells were co-transfected with mGFP tagged K-RasG12V and mCherry tagged PDE6D. Transfected cells were treated with 0.1% dimethyl sulfoxide (DMSO) control or 5 μ M Deltafloxin-1, 17, 14, Deltarasin, or 500 nM FTI-277 for 24 h; $n = 3$. (B,C) Ras membrane organization measured with nanoclustering-FRET in HEK cells coexpressing mGFP or mCherry tagged K-RasG12V (B) or mGFP or mCherry tagged H-RasG12V (C). Cells were cotransfected with siRNA-PDE6D for 48 h or treated with 0.1% DMSO control, 5 μ M Deltafloxin-1, 17, 14, Deltarasin, or 0.2 μ M FTI-277 for 24 h; $n = 3$. (D) K-Ras nanoclustering-FRET dose response curve of Deltafloxin-1 or Deltarasin. Cells were treated for 24 h; $n = 3$. The numbers on the bars indicate numbers of analyzed cells. Graphs show mean values \pm SEM. Statistical significance levels are annotated as **** $p < 0.0001$; ns, not significant.

additional cellular FRET-assay that detects FRET due to nanoscale clustering (nanoclustering-FRET) of Ras oligomers, including dimers, on the membrane.²¹ We previously demonstrated that nanoclustering-FRET can quantify subcellular distribution changes that may be difficult to establish by confocal imaging (Figure S2C).^{22,23} Thus, we confirmed that FTI selectively affects H-Ras membrane anchorage more than that of K-Ras, as the latter can be alternatively prenylated by geranylgeranyltransferase I^{2,24} (Figure 2B,C). Given that rate-limiting steps of the PDE6D-mediated trafficking cycle selectively facilitate plasma membrane anchorage of K-Ras, but not H-Ras, knockdown of PDE6D selectively reduced the K-Ras but not H-Ras nanoclustering-FRET (Figures 2B,C and S2D). By contrast, the reference PDE6D-inhibitor, Deltarasin, reduced FRET of both Ras isoforms about equally. This indicates pan-Ras-directed, off-target effects of Deltarasin that may underlie its relatively high general toxicity.¹⁶ Deltafloxin-1 on the other hand selectively reduced K-RasG12V but not H-RasG12V FRET as expected (Figure 2B,C). This was confirmed with the three linkage derivatives, further corroborating the flexibility at this position in our generic design (Figure S2E,F). Importantly, Deltafloxin-1 demonstrated an in cellulo potency in this FRET-assay [$IC_{50}(15) = 1.65 \pm 0.95 \mu$ M (mean \pm standard error of the mean (SEM))] that was comparable to the in vitro affinity ($K_d = 3.61 \pm 0.02 \mu$ M), although it was not as potent as Deltarasin in cellulo [Figure 2D, $IC_{50}(\text{Deltarasin}) = 0.7 \pm 0.4 \mu$ M (mean \pm SEM)].

Previous work suggested that the pharmacological stability of the cell penetration group can be tuned within the esterase cleavable S-acyl moiety by the electronegativity of the 2-substituent, such as ethoxycarbonyl (relatively labile) or methyl (more stable).²⁰ Indeed, heating of Deltafloxin-1 before application to cells decreased its cellular activity to a level similar to that of 14 or 19, which both do not have the cell penetration group (Figure S2G).

In conclusion, these results demonstrate that the hexyl-spring and cell penetration group enable a similar in cellulo potency of Deltafloxin-1 as observed in vitro. Importantly, Deltafloxin-1 acts on-target in cells allowing for a selective inhibition of K-Ras activity, whereas the reference compound Deltarasin affects equally K-Ras and H-Ras.

Deltafloxin-1 Selectively Inhibits Oncogenic K-Ras Driven Cell Proliferation and Tumorsphere Formation.

In order to further validate the K-Ras selectivity in cells, we examined the effect of Deltafloxin-1 and derivatives on 2D proliferation of colorectal cancer cell lines. Deltafloxin-1 inhibited the K-RasG13D mutated HCT116 ($IC_{50} = 11 \mu$ M, CI 95% 8.1–16 μ M) significantly more than the Ras wt HT-29 cell line ($IC_{50} = 40 \mu$ M, CI 95% CI 25–72 μ M, $p < 0.0001$) (Figure 3A,B). Similar micromolar activities and oncogenic K-Ras selectivity ($p < 0.0001$) were also seen in the K-RasG13D-mutated and -dependent MDA-MB-231 ($IC_{50} = 7.2 \mu$ M, CI 95% 5.1–9.7 μ M) and H-RasG12D-mutated and -dependent Hs 578T ($IC_{50} = 21 \mu$ M, CI 95% 13–35 μ M) breast cancer cell lines (Figure S3A,B,G). Both activity and K-Ras selectivity in colon and breast cancer cells were corroborated by Deltafloxin-1 linkage derivatives (Figure S3C–F).

Thus, half-maximal inhibition of K-Ras-mutant cancer cell viability by Deltafloxin-1 occurred at approximately 7- to 11-fold higher concentrations than in the cellular K-Ras nanoclustering-FRET assay, which also means that the in vitro and cancer cell inhibitory activities were very similar. By contrast, the difference between cellular inhibition and in cellulo on-target activity of the bis-sulfonamide inhibitor Deltasonamide 2 was 12- to 25-fold, while an even greater difference is apparent for this compound when compared to the in vitro affinity (650- to 1300-fold).¹⁷ It is plausible to assume that the better in vitro/cell inhibition activity relation of Deltafloxin-1 compared to Deltasonamide 2 is due to its spring moiety.

While these results demonstrate selectivity for cancer cells expressing mutant K-Ras, the comparison of proliferation in 2D is not as discriminatory as the nanoclustering-FRET assay. However, in the past, we established that compounds which selectively decrease K-Ras, but not H-Ras-nanoclustering-FRET, have a high potential as inhibitors of stemness properties of cancer cells, as measured by the formation of tumorspheres.^{22,25} Accordingly, the selective effect of PDE6D on K-Ras but not H-Ras (Figure 2B,C) makes PDE6D a good target to enable such anticancer stemness activity. Indeed, tumorsphere formation of K-RasG12V, but not H-RasG12V transfected or control HEK cells,²⁶ was selectively decreased after knockdown of PDE6D (Figure S3H–J). Similarly, mammospheres derived from K-Ras mutant MDA-MB-231 were inhibited by Delta-

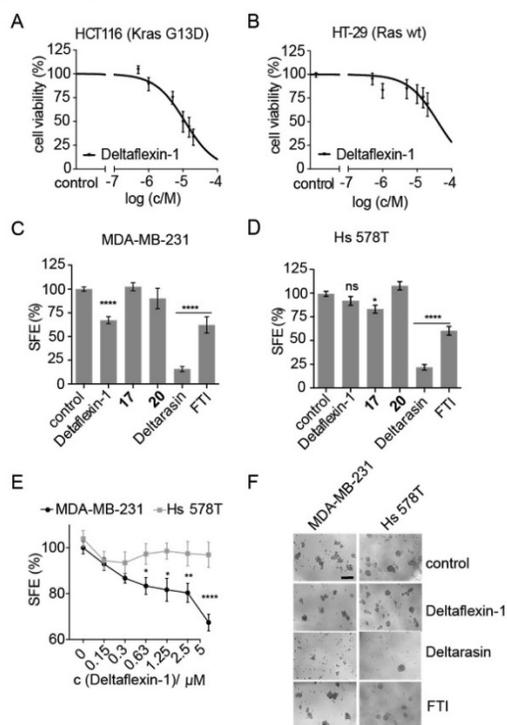

Figure 3. Deltaflexin-1 selectively inhibits oncogenic K-Ras-driven cell proliferation and mammosphere formation. (A,B) Dose-dependent cell viability in response to 72 h treatment with Deltaflexin-1 at concentrations ranging from 0 to 20 μM in HCT116 cells (A) and HT-29 cells (B). Graphs show mean values \pm SEM, $n = 4$. (C,D) Sphere formation efficiency (SFE) of MDA-MB-231 cells (C), $n = 11$, and Hs 578T cells (D), $n = 7$, cultured in suspension culture for 6 days, followed by a 72 h incubation with 5 μM Deltaflexin-1 or Deltarasin, 0.5 μM FTI or 0.1% DMSO control. Graphs show mean values \pm SEM. (E) Deltaflexin-1 dose-dependent effect on SFE with the same protocol as in (C,D). Graphs show mean values \pm SEM, $n = 4$. The SFE is significantly different between MDA-MB-231 and Hs 578T above 0.63 μM . (C–E) Statistical significance levels are annotated as ns, not significant; * $p < 0.05$; ** $p < 0.01$; *** $p < 0.0001$; ns, not significant. (F) Representative images of MDA-MB-231 and Hs 578T spheroids at day 10 of suspension culture, after indicated treatments as in (C,D). Scale bar of 200 μm is representative for all images.

flexin-1 more significantly than those of H-Ras mutant Hs 578T (Figure 3C–F). Control compounds 17 and 20 with a stiff or shortened linker, respectively, had no significant effect (Figure 3C,D). This K-Ras-mutant mammosphere selectivity was largely confirmed with the Deltaflexin-1 linkage derivatives (Figure S3K,L), nevertheless suggesting some off-target effects on tumor sphere growth by the different linkages.

Second Generation Deltaflexins with Improved Chemotype. Encouraged by these results, a second generation of inhibitors was developed based on Deltaflexin-1. We replaced the potentially toxic coumarin moiety with a substituted terephthalic acid moiety, thus generating a partial hybrid with a bis-sulfonamide Deltasonamide inhibitor (compound 8¹⁷) (Figure 4A). In addition, the bottom moiety was varied to characterize the activity of the pharmacologically more stable 2-

methyl-substituent on the S-acyl cell penetration group. While compound 23 with the more stable bottom-moiety had a comparable affinity to 15, its analogue 22 bound with a 2.6-fold lower affinity (Figure 4B, Table 1, Figure S4A, Table S1).

Computational docking supported these data, as overall similar positioning and similar contacts as for Deltaflexin-1 were observed for the second-generation compounds in the PDE6D pocket (Figure S4B). It appeared though that the substitution of the top moiety from an aromatic two-ring system to one aromatic ring allowed for more flexibility of the top moiety orientation. Moreover, the potential for a new hydrogen bond with Ser115 was identified for both 22 and 23. In addition, the bending of 23 could contribute to the formation of an additional hydrogen bond with Glu88, which is not observed in 22 (Figure S4B). The relative strengths of these interactions may contribute to the observed differences in the binding affinities.

In agreement with the in vitro data, second-generation compound 23 performed as well as 15 and somewhat better than 22 in disrupting the K-RasG12V/PDE6D interaction as assessed by FRET-experiments in cells (Figure 4C). Similarly, amongst the 4*n*-methylene-linker counterparts of 22 and 23, 25 performed better than 24 (Figure 4A,C). These data further support that the replacement of the relatively labile 2-ethoxycarbonyl with the more stable 2-methyl on the S-acyl cell penetration group is beneficial. Finally, 22 and 23 (hereafter named Deltaflexin-2) led to a significant dose-dependent reduction of the K-RasG12V nanoclustering-FRET compared with 24 and 25 (Figure 4D). No effect on H-RasG12V FRET was observed (Figure S4C).

Recently, exquisite K-RasG12C selectivity was demonstrated for the covalent inhibitor ARS-1620.⁷ In agreement with a significant overall activity, quantitative scoring of the chemical inhibition of PDE6D with Deltaflexin-2 revealed that it had 70% activity of ARS-1620 in KRAS-G12C mutant NCI-H358 lung cancer cells grown as tumorspheres. Moreover, Deltaflexin-2 was inactive in the B-RafV600E mutant A375 lung metastasis melanoma cell line, as was ARS-1620 (Figure 4E). These data confirm that Deltaflexins significantly inhibit cell spheroid growth in a K-Ras selective manner. By contrast, no such selectivity was found for Deltarasin, which showed equally high activity in both cell lines, again suggesting a general off-target toxicity.

Similarly, K-RasG13D-mutant MDA-MB-231- but not H-RasG12V-mutant Hs 578T-mammosphere formation was selectively decreased by Deltaflexin-2, while the counterpart with the shorter flexible linker 25 was inactive (Figure S4D,E). In line with the Ras-mutation status, the mammosphere formation of MDA-MB-231 and Hs 578T was selectively abrogated by the knockdown only of the mutated Ras isoform (Figure S4F–I), confirming that this assay can report on the selectivity for oncogenic K-Ras (MDA-MB-231) or H-Ras (Hs 578T). However, knockdown of PDE6D strongly affected sphere formation of both cell lines (Figure S4F,G).

We therefore conclude that Deltaflexins can block stemness traits of cancer cells and have a clear in cellulo selectivity for K-Ras as compared to H-Ras. However, our data also suggest that the stemness inhibiting activity of PDE6D inhibitors depends at least in breast cancer cell lines on other clients or activities of PDE6D.

In this work, we have demonstrated that the attachment of a “chemical spring” and cell penetration group to a generic heterocycle enables the de novo design of low micromolar PDE6D inhibitors in the first generation. This redesign approach is strikingly simple and together with the flexible

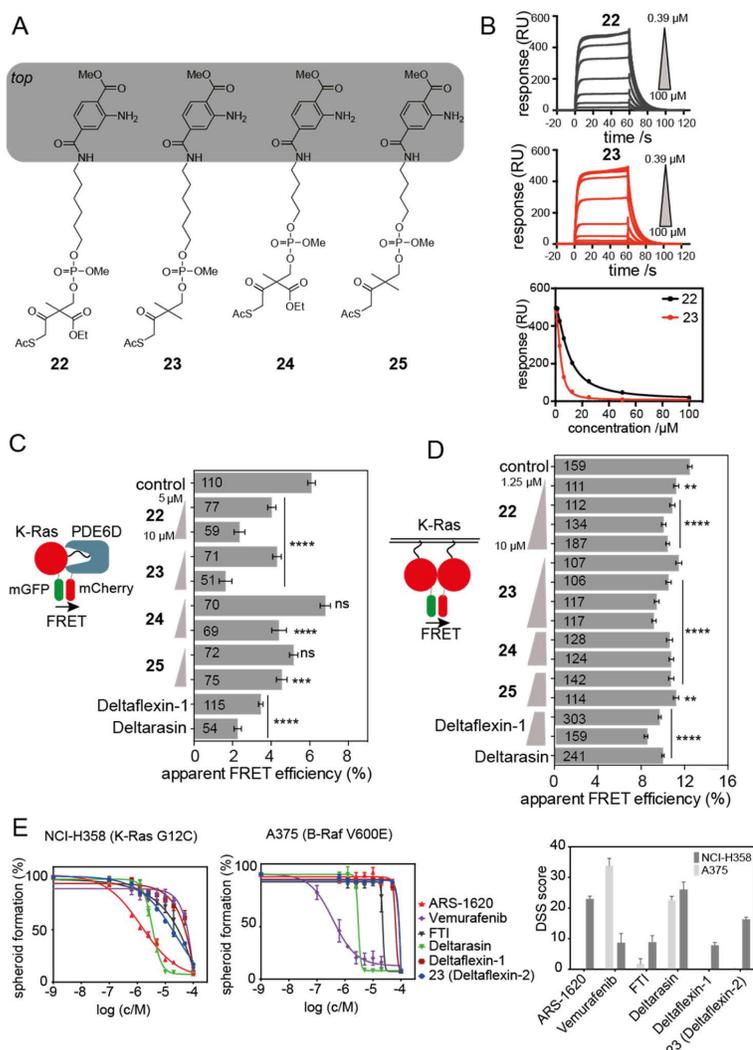

Figure 4. Partial scaffold hybridization creates second-generation inhibitors. (A) Second-generation compounds have an altered “top” moiety taken from a previously published PDE6D inhibitor. Note the variation of the protecting group between **22** and **23**, as well as **24** and **25**. Linker length is varied between the **22**, **23** vs **24**, **25**. (B) SPR data of avi-K-RasFMε/PDE6D treated with **22** and **23** (Deltaflexin-2) and dose response curves constructed from SPR kinetic data; $n = 3$. (C) PDE6D/K-Ras interaction by FLIM-FRET. HEK cells were cotransfected with mGFP-tagged K-RasG12V and mCherry-tagged PDE6D. Transfected cells were treated with 0.1% DMSO control or 5 μM ($n = 3$) and 10 μM ($n = 1$) compounds **22**, **23**, **24**, **25**, or 5 μM Deltaflexin-1, Deltarasin for 24 h; (D) K-Ras membrane organization measured with nanoclustering-FRET in HEK cells coexpressing mGFP or mCherry tagged K-RasG12V for 48 h or treated with 0.1% DMSO control, and various concentrations of compounds **22**, **23**, **24**, **25**, or 5 μM Deltaflexin-1, Deltarasin for 24 h; $n = 3$. For all FRET-data, the numbers on the bars indicate the number of analyzed cells. (E) Dose-dependent cell viability of lung cancer cell lines, NCI-H358 and A375 grown as spheroids under low attachment and serum free conditions in response to 72 h treatment with ARS-1620, Vemurafenib, FTI-277, Deltarasin, Deltaflexin-1, and Deltaflexin-2 at concentrations ranging from 0 to 20 μM; $n \geq 3$. Higher efficacy results in a higher drug sensitivity score (DSS), an area under the curve (AUC) metric. Graphs show mean values \pm SEM. Statistical significance levels are annotated as $**p < 0.01$; $***p < 0.0001$; ns, not significant.

coupling chemistry should allow for improvements of existing PDE6D inhibitors. As validated by the second-generation compounds, our approach is compatible with compound-scaffold hybridization of existing PDE6D compounds. Thus, we expect to quickly advance the development of more potent derivatives in the near future. Moreover, our strategy may apply

to inhibitors of closely related targets, such as UNC119,²⁷ in addition to PDE6D inhibitors.

Past generations of PDE6D inhibitors underwent substantial structure-based optimization to arrive at sub and low nanomolar in vitro activities, but surprisingly they exhibited ~1000-fold less antiproliferative potential in cancer cells. Thus, the relation of

Deltaflexin-2 in vitro and in cellulo potencies is ~60- to 180-times better than that of Deltasonamide-2. Moreover, as compared to Deltarasin, Deltaflexins demonstrated the expected selectivity for K-Ras over H-Ras in cells. Therefore, the current Deltaflexins can serve as valuable tool compounds to investigate the PDE6D associated anticancer mechanisms. While we demonstrate the K-Ras selectivity of Deltaflexins, the comparison of PDE6D- and KRAS-knockdown data suggests K-Ras-independent effects of PDE6D inactivation on stemness traits of cancer cells. Other activities of PDE6D or clients other than K-Ras could be important in this context. For example, the PDE6D client INPP5E (inositol polyphosphate-5-phosphatase E) localizes to the primary cilium in a PDE6D-dependent manner.^{28–30} In line with a potential contribution of INPP5E inhibition to the antistemness effect, primary ciliogenesis and associated Hedgehog signaling have recently been linked to epithelial–mesenchymal transition and stemness promotion in triple negative breast cancer.³¹

Nonetheless, K-Ras overactivity appears to be an important biomarker for the efficacy of PDE6D inhibitors.³² In order to establish the exact therapeutic spectrum of the single-agents, a broader panel of cancer cells should be tested with PDE6D inhibitors in the future. Given that carboxymethylation of the prenylated C-termini of small GTPase clients provides additional affinity, it is foreseeable that concurrent inhibition of isoprenylcysteine carboxyl methyltransferase, by inhibitors such as cysmethynil, will be synergistic with PDE6D inhibitors.^{12,32}

While targeting of signaling or trafficking hubs, such as PDE6D, could intuitively lead to more side effects, this approach may in the end be advantageous from the drug development point of view. Given that different cancer types and subtypes have diverse sets of drivers,^{33,34} drugs that target a hub may affect several cancer drivers at once. Such hub inhibitors may therefore be more easily applicable to several types of cancer. This strategy is, for example, pursued for inhibitors of Hsp90, which is a major hub of kinases.^{35,36} Irrespective of their exact mechanism of action, PDE6D inhibitors therefore remain attractive as potential cancer drugs.

METHODS

DNA Constructs and siRNA. Plasmids pmGFP/mCherry-H-RasG12V and pmGFP/mCherry-K-RasG12V were previously described.^{22,23} Plasmids for mCit-Rheb and mCherry-PDE6D were previously described.¹¹ The human gene-directed siRNAs were purchased from Dharmacon as ON-TARGET plus SMART siRNA pools. The catalogue numbers are as follows: scrambled siRNA (cat. no. D-001810-10-05), human KRAS (cat. no. L-005069-00, lot 170710), human HRAS (cat. no. L-004142-00, lot 160414), and human PDE6D (cat. no. L-004310-00). Opti-MEM and transfection reagents Lipofectamine 3000 (cat. no. L3000001) and RNAiMAX (cat. no. 13778030) were purchased from Thermo Fisher Scientific. JetPrime (cat. no. 114-75) was obtained from Polyplus, Illkirch-Graffenstaden, France. FuGENE HD (cat. no. E2311) was purchased from Promega Biotech AB, Nacka, Sweden.

Cell Culture. HEK293 EBNA cells were kind gift of Prof. Florian M Wurm, EPFL, Lausanne, Switzerland. MDA-MB-231, Hs 578T, HCT116, HT-29, NCI-H358, and A-375 cell lines were obtained from ATCC. HEK293 EBNA, Hs 578T, HCT116, and HT-29 cell lines were maintained in Dulbecco's modified Eagle's medium (DMEM, cat. no. D6171, Sigma-Aldrich, Helsinki, Finland), supplemented with 10% fetal bovine serum (FBS) (cat. no. S1810, Biowest, Nuaille, France) and 2

mM L-glutamine (cat. no. G7513, Sigma-Aldrich). MDA-MB-231, NCI-H358, and A375 cells were cultured in Roswell Park Memorial Institute medium (RPMI, cat. no. R5886, Sigma-Aldrich), containing 10% FBS and 2 mM L-glutamine. All cells were incubated at 37 °C, with 5% CO₂, in a humidified cell incubator. Cells were subcultured twice a week.

Fluorescence Lifetime Imaging Microscopy-FRET. HEK293 EBNA cells were seeded in 12-well plates onto sterile coverslips. The next day, cells were transfected using FuGENE HD or jetPRIME transfection reagent with a total of 800 ng of plasmids. For donor samples, cells were transfected with mGFP or mCitrine-tagged plasmid. In FRET pairs, donors and acceptors were transfected at a 1:3 ratio. Acceptors were mCherry-tagged Ras plasmids in the nanoclustering-FRET experiments for membrane organization studies. For interaction studies, pmGFP-K-RasG12V and pmCherry-PDE6D, or pmCitrine-Rheb and pmCherry-PDE6D, were used all at the same 1:3 ratios with a total of 800 ng plasmids being used in each experiment. After 24 h of transfection, cells were treated with either 0.1% DMSO control or various concentrations of test compound or Deltarasin (cat. no. 9001536, Cayman Chemical, Tallinn, Estonia), or FTI-277 (cat. no. Sc-215058, Santa Cruz Biotechnology, Dallas, USA) or FTI-2628 (cat. no. sc-221635, Santa Cruz Biotechnology) for 24 h and fixed in 4% paraformaldehyde (PEA) before mounting with Mowiol 4-88 (cat. no. 81381, Sigma-Aldrich). The donor fluorescence lifetime was measured using a fluorescence microscope (Zeiss AXIO Observer D1) with a fluorescence lifetime imaging attachment (Lambert Instruments, Groningen, The Netherlands), as previously described in refs 37, 38. The fluorescence lifetime of at least 40 cells per treatment was measured in each experiment. The percentage of the apparent FRET efficiency (E_{app}) was determined using the measured lifetimes of donor–acceptor pairs (τ_{DA}) of samples and the average donor lifetime (τ_D), based on the equation: $E_{app} = (1 - \tau_{DA}/\tau_D) \times 100\%$.

Tumorsphere Assays. Mammosphere formation assays were performed in F-bottom 96-well suspension culture plates (cat. no. 655185, Cellstar, Greiner Bio-One, Frickenhausen, Germany). 1500 cells per well were seeded in 50 μ L DMEM or RPMI medium containing 1 \times B27 (cat. no. 17504044, Gibco, Thermo Fisher Scientific), 25 ng/mL EGF (cat. no. E9644, Sigma-Aldrich), and 25 ng/mL FGF (cat. no. RP-8628, Thermo Fisher Scientific). Cells were cultured for 6 days and then treated with test compounds or DMSO control (0.1% v/v) for additional 3 days. The cells were resupplemented with fresh growth medium every 2 days. For knockdown experiments and for K-Ras and H-Ras transfections, cells were seeded in 6-well plates and treated with either 50 nM scrambled siRNA or siRNA targeting PDE6D KRAS or HRAS or with mGFP-K-RasG12V or mGFP-H-RasG12V plasmids, using jetPRIME transfection reagent or Lipofectamine 3000. On the next day, cells were replated into 96-well plates for suspension cell culture. Mammosphere formation was analyzed under an EVOS FL microscope (Thermo Fisher Scientific) and spheres exceeding 50 μ m in diameter were counted. The SFE was expressed as percentage normalized to vehicle-treated control. In protein overexpression or knockdown experiments, SFE was normalized to the empty vector or scrambled siRNA-transfected controls, respectively.

Tumorspheres of lung cancer cells were generated by seeding NCI-H358 or A-375 cells (1500 cells per well) as a suspension culture in F-bottom 96-well suspension culture plates (cat. no. 655185, Cellstar, Greiner Bio-One) in 50 μ L

RPMI medium supplemented with 0.5% methylcellulose, 25 ng/mL EGF, 25 ng/mL FGF, 1× B-27 supplement, and 2 mM L-glutamine. Cells were initially grown for 72 h and treated with freshly thawed compounds. After another 72 h of incubation, the cell viability was assessed using the alamarBlue assay (cat. no. DAL1100, Invitrogen, Carlsbad, CA, USA). A 10% final volume of alamarBlue reagent was added to each well of the plate and incubated for 4 h at 37 °C. Then, the fluorescence intensity was measured using a FLUOstar OPTIMA plate reader (BMG Labtech, Germany) with an excitation wavelength of 560 ± 5 nm and emission wavelength of 590 ± 5 nm. The obtained fluorescence intensity data were normalized to DMSO control. To quantitatively profile the drug sensitivity from the dose-response data, the DSS algorithm was employed.³⁹ The DSS score was calculated according to the formula

$$\text{DSS} = \frac{100 \times \text{AUC}}{\text{TA} \times \log a}$$

The curve fitting parameters were used to calculate the AUC relative to the total area (TA) between the 10% threshold (DMSO at 0.1%) and 100% inhibition (benzethonium chloride at 100 μM). The integrated response is divided by the logarithm of the top asymptote ($\log a$).

2D Cell Viability Assay. Hs 578T, HCT-116, and HT29 cells were plated onto 96-well cell culture plates at a density of 500 cells/well and allowed to attach for 24 h. Freshly thawed aliquots of test compounds were then added ice-cold at indicated concentrations. DMSO (0.1% v/v) was used as control. Plates were further incubated for 72 h. The cell viability was assessed using the alamarBlue reagent, according to manufacturer's instructions. The fluorescence intensity was read with the excitation wavelength of 530 ± 10 nm and emission wavelength of 590 ± 10 nm using a Synergy HI plate reader (BioTek, Winooski, VT, USA).

Western Blotting. Cells were lysed in RIPA buffer (cat. no. 89900, Thermo Scientific) containing protease (cat. no. 88666, Thermo Scientific) and phosphatase inhibitors (cat. no. 0496845001, Roche, Mannheim, Germany) and then sonicated for 5 min in ice-cold water. Proteins were separated on 10% sodium dodecyl sulfate polyAcrylamide gel electrophoresis (SDS-PAGE) gels and transferred to nitrocellulose membranes (cat. no. NBA 083C001EA, Protran, Waltham, USA) using a Transferblot Turbo Transfer System (Bio-Rad, Hercules, CA, USA). Briefly, the membranes were blocked in 1×TBS containing 0.1% Tween-20 and 5% w/v nonfat dry milk for 30 min and incubated with primary antibodies PDE6D (cat. no. sc-166854, Santa Cruz Biotechnology, Paso Robles, CA, USA.) or β -actin (cat. no. A1978, Sigma-Aldrich) overnight, at 4 °C. The membranes were then incubated with secondary antibodies antimouse (cat. no. sc-2954, Santa Cruz Biotechnology) for 1 h at room temperature. Protein bands were detected using a ChemiDoc MP instrument (Bio-Rad) after treatment with ECL reagent (cat. no. 170-5061, BioRad). The protein-band intensities were measured using Image Lab software (Bio-Rad).

RT-qPCR Analysis for Gene Knockdowns. MDA-MB-231 and Hs 578T cells were seeded in 6-well plates and transfected with 50 nM of siRNA KRAS or HRAS or scrambled, negative control siRNA (QIAGEN, cat. no. 1022076, QIAGEN, Hilden, Germany) using Lipofectamine. After 24 h of transfection, total RNA was isolated using NucleoZol according to the manufacturer's protocol (cat. no.: 7040404, Macherey-Nagel, Hoerd, France). Reverse transcription was performed with 1 μg of total RNA using SuperScript III Reverse

Transcriptase (cat. no.: 18080093, Invitrogen). The knock-downs of KRAS and HRAS gene transcripts were analyzed by real-time qPCR using SsoAdvanced Universal SYBR Green Supermix (Bio-Rad), on the CFX-connect real-time PCR instrument (Bio-Rad). The transcripts were selectively amplified using specific primers producing amplicons for KRAS (total) and HRAS. The gene β -actin was used as reference. The following primers were used: for KRAS (total), forward 5'-tacagtgcattgaggaccac-3', reverse 5'-tcctgagcctgtttgtgtct-3' (amplicon 206 bp); for HRAS, forward 5'-ctgacatccagctgatcca-3', reverse 5'-tggcaaacacacaggaag-3' (amplicon 196 bp); for ACTB (β -actin), forward 5'-ggggtgttgaggtctcaaa-3'; reverse 5'-ggcatcctcacctgaagta-3'.⁴⁰

Confocal Imaging. MDCK cells, stably overexpressing mGFP-KRasG12V, were seeded onto coverslips in 12-well cell culture plates. The cells were treated with 0.1% DMSO control or 5 μM Deltarasin or Deltaflexin-1. After 24 h cells were fixed in 4% PFA and mounted with Mowiol, cells were imaged using a laser scanning microscope (LSM 780) Carl Zeiss Microscopy, Jena, Germany.

Compound Syntheses. Purchased compounds were used without further purifications. Chemicals and solvents were purchased from the companies Sigma-Aldrich, VWR, and Thermo Fisher Scientific. Solvents were dried over 3 or 4 Å molecular sieves. Commercially available solvents for semi-preparative high-performance liquid chromatography (HPLC) (acetonitrile HPLC grade) were used. Solvent mixtures are understood as volume/volume. Extended information on the complete compound syntheses and analytics are described in Supporting Information S1.

Molecular Modeling. Docking studies were carried out by the GOLD module⁴¹ of Discovery Studio 4.5 (Accelrys Inc. San Diego, USA, <http://www.accelrys.com/>) using the crystal structure of PDE6D determined at 1.45 Å resolution (PDB code 4JV8)¹⁵ as the receptor molecule. Water molecules and the bound ligand were removed from the structure prior to the docking. Binding sites were identified by using the binding site identification tool in Discovery Studio. The binding site that matched also the binding site identified by the crystal structure was selected for docking. The ligands were generated with ChemDraw Professional 15.1 (PerkinElmer Informatics, www.cambridgesoft.com) and exported as *.mol files to the Discovery Studio. Hydrogen atoms were added to the protein and the ligand. The Goldscore fitness function was used to score the poses.

SPR Binding and Inhibition Assays. SPR binding experiments were performed on a Biacore S200 instrument (GE Healthcare Life Sciences, Marlborough, MA, USA) as described previously.⁴² Farnesylated and methylated K-Ras-GDP (K-RasFMe), with an N-terminal avi-tag, was captured on neutravidin-coupled CM5 sensor chips (capture density 500–1500 RU). PDE6D (2-fold serial dilution, 20–0.039 μM) was injected over the K-RasFMe surface in 20 mM *N*-(2-hydroxyethyl)piperazine-*N'*-ethanesulfonic acid (HEPES) (pH 7.5), 150 mM NaCl, 0.01%, Tween 20, 5 mM MgCl₂, and 5% DMSO at 30 $\mu\text{L}/\text{min}$ and with a contact time of 60 s. The inhibitory activity of compounds for PDE6D/K-RasFMe interaction was measured using 1.25 μM PDE6D and a serial dilution of compound (2-fold, 100–0.39 μM) using the same buffer and flow rate. PDE6D (1.25 μM) was diluted with Deltarasin (3-fold, 50 μM to 68 nM) was used as a positive control. All titrations were run over three flow cells with variable surface densities of K-RasFMe. The data were processed by

subtracting binding responses on the reference flow cells as well as the buffer subtraction. The samples were also corrected for DMSO mismatches using a DMSO standard curve. The equilibrium binding constant and IC_{50} values were calculated using the Biacore S200 Evaluation software. The IC_{50} value obtained from SPR and FA assay was converted into K_d using a modified Cheng–Prusoff equation

$$K_d = \frac{IC_{50}}{1 + \frac{[L]}{K_D}}$$

where K_D is the dissociation constant between PDE6D/K-RasFMe and $[L]$ is the concentration of PDE6D used in SPR experiments.⁴⁴

FA Assay. The binding of compounds to PDE6D was assessed in an FA assay using fluorescein-tagged farnesylated Rheb (F-Rheb) peptide as the probe.^{14,43} PDE6D was produced as described below. FA assays were performed on a black low volume, round-bottom, non-binding surface 384-well plate (Corning #4514) in an assay buffer composed of 30 mM Tris, 150 mM NaCl, and 3 mM dithiothreitol. To a three-fold dilution of compounds in assay buffer (300 μ M to 1.7 nM), a complex of 0.25 μ M F-Rheb peptide and 2 μ M PDE6D was added, and the reaction mix was incubated for 15 min at RT. Then, the FP was recorded on a Synergy H1 hybrid plate reader (BioTek) equipped with a polarization cube with an excitation wavelength of 485 \pm 10 nm and emission wavelength of 528 \pm 10 nm. The FP data were plotted against the logarithmic concentration of compounds and fit to log inhibitor vs response–variable slope (four parameters) equation in Prism (GraphPad), and the IC_{50} was determined.

Cloning, Expression, and Purification of Recombinant Proteins. PDE6D was recombinantly produced in *Escherichia coli* BL21 (DE3) transformed with pDest-His6-MBP-PDE6D grown at 37 °C until OD of 0.6–0.8 and then induced with 0.5 mM of β -D-1-thiogalactopyranoside overnight at 16 °C.¹² The bacterial lysate was prepared in a binding buffer (20 mM HEPES, pH 7.6, 300 mM NaCl, 5 mM MgCl₂, 1 mM TCEP (Tris(2-carboxyethyl)phosphine hydrochloride), and protease inhibitor tablet from Roche) containing 0.5 mg/mL of lysozyme. Soluble proteins were isolated after sonication and centrifugation steps. The protein His6-MBP-TEV-PDE6D was purified on HisTrap HP column (GE Healthcare) in binding buffer containing imidazole and eluted with a 20 column-volume gradient from 35 to 500 mM imidazole. The eluted fractions were analyzed on SDS-PAGE. The fractions containing His6-MBP-TEV-PDE6D were treated with tobacco etch virus (TEV) protease (cat. no.: T4455, Sigma-Aldrich) (1:25 w/w, TEV/fusion protein) for 1 h at room temperature and then dialyzed overnight in binding buffer without protease inhibitor. The cleavage product containing His6-MBP and PDE6D was loaded a second time on a HisTrap HP column in binding buffer. The peak fractions (OD280) corresponding to the nonbound protein PDE6D were collected, pooled, concentrated using Amicon Ultra Centrifugal Filters (Merck Millipore, Molsheim, France), and analyzed on a SDS-PAGE gel with Coomassie blue. The presence of purified PDE6D was confirmed by Western blotting using a monoclonal anti-PDE6D antibody (cat. no.: sc-376724, Santa Cruz Biotechnology; dilution ratio 1:200).

The baculovirus expression vector for production of processed K-Ras4B has been previously described.⁴⁴ An avi-tagged full-length K-Ras4B clone was generated by introducing an avi sequence (LNDIFEAQKIEWG) between the TEV

protease cleavage site (ENLYFQG) sequence and amino acids 2–188 of K-Ras4B. The baculovirus expression vector for the production of processed avi-K-Ras4B was produced using the methods described previously.⁴⁴ Expression of farnesylated and carboxymethylated K-Ras4B (K-RasFMe) and avi-K-Ras-FMe followed the methods as described.⁴² Purification of processed avi-tagged full-length K-Ras4B was as described⁴⁴ with modifications. Protein isolated after the removal of the N-terminal His6-MBP tag (21.5 μ M avi-K-Ras-FMe) was biotinylated by incubating for 2 h at room temperature with 2.8 μ M His6-BirA, 3.6 mM ATP, 215 μ M biotin in a buffer of 20 mM HEPES, pH 7.3, 300 mM NaCl, 5 mM MgCl₂, 1 mM TCEP (Tris(2-carboxyethyl)phosphine hydrochloride), and 1:1000 v/v protease inhibitor (P8849 Sigma-Aldrich). The reaction was then dialyzed at 4 °C for 16 h against 20 mM HEPES, pH 7.3, 300 mM NaCl, 5 mM MgCl₂, and 1 mM TCEP. The dialyzed reaction was passed over a HisTrap FF column (GE Healthcare), equilibrated with dialysis buffer, to remove His6-BirA. The biotinylated avi-K-Ras-FMe has a slight affinity for the column and elutes from the column at low (<50 mM) imidazole concentrations. Fractions were analyzed by coomassie-stained SDS-PAGE, and positive fractions were pooled and dialyzed against 20 mM HEPES, pH 7.3, 300 mM NaCl, 1 mM MgCl₂, and 1 mM TCEP for 3 h at room temperature. The protein concentration was determined by absorbance at 280 nm, and aliquots were snap frozen in liquid nitrogen and stored at –80 °C.

Statistical Analysis. GraphPad Prism software was used for the statistical analysis. The sample size n for each data set is provided in the relevant figure legends and represents independent experiments. Unless otherwise stated, statistical significance was evaluated with the Student's t -test or One-way ANOVA complemented by multiple comparison post hoc tests, as appropriate. A p -value of <0.05 is considered statistically significant, and the statistical significance levels are annotated as * = $p < 0.05$; ** = $p < 0.01$; *** = $p < 0.001$; **** = $p < 0.0001$, or ns = not significant.

Author Contributions

F.A.S. designed, performed, and analyzed all FLIM-FRET and WB experiments. C.A. and S.O. designed, performed, and analyzed sphere formation and cell proliferation experiments. A.S., O.M.A., H.L., M.O., and P.V. collaboratively designed the

compounds **5**, **9**, **13**, and **15**. M.O., P.V., P.R., and D.A. collaboratively designed the compounds **17**, **19**, **20**, **22**, **23**, **24**, and **25**. A.S. and P.R. prepared the compounds under supervision of M.O. M.C. prepared PDE6D protein. G.b.M. performed and analyzed FA experiments. L.B. and A.G.S. designed, performed, and analyzed SPR experiments. T.T. prepared avi-KRasFMe. A.C.P. performed computational docking and prepared graphs of structures. M.O. and P.V. wrote the chemical synthesis description. D.A. conceived the study, designed experiments, interpreted results, and wrote the manuscript together with F.A.S. All authors commented on the manuscript.

Funding

This work was supported by a CIMO fellowship to A.S. and F.A.S. P.V. received the support from the Academy of Finland Project (#308931). D.A. received the support from the Academy of Finland Key Project (#304638) grant, the Sigrid Juselius Foundation, and the Cancer Society of Finland.

Notes

The authors declare the following competing financial interest(s): We have filed a patent around second generation inhibitor Deltaflexin-2.

ACKNOWLEDGMENTS

The authors are grateful for the support from the cell imaging core (CIC, Turku Bioscience Centre, Turku, Finland). The infrastructure support from BioCenter Finland is acknowledged. We thank Prof. Philippe I. H. Bastiaens (Max-Planck Institute Dortmund, Germany) for providing the mCitrine-Rheb and mCherry-PDE δ constructs. We thank Lange Yakubu Saleh for the synthesis of compound **20** and Anuer Al-Rammahi for the synthesis of compound **17**. We thank Eyad K. Fansa (Max-Planck Institute Dortmund, Germany) for providing the F-Rheb peptide. We acknowledge the protein production support for avi-KRAS-FMe and KRasFMe from Vanessa Wall, Matt Drew, and Jennifer Mehalko and Dominic Esposito for providing the pDest-His6-MBP-PDE6D plasmid (NCI-RAS Initiative, Frederick National Laboratory for Cancer Research, USA). This project was funded in whole or in part with federal funds from National Cancer Institute, NIH Contract HHSN261200800001E. The content of this publication does not necessarily reflect the views or policies of the Department of Health and Human Services, and the mention of trade names, commercial products, or organizations does not imply endorsement by the US Government.

SYNTHESES

Seven different coumarin-phosphate derivatives (**5, 9, 13, 15, 17, 19** and **20**, Figure S4 and Scheme 1) and four terephthalic acid-phosphate derivatives (**22, 23, 24** and **25**, Figure S4), bearing a bioactivatable and thermolabile phosphate protecting groups (4-acetylthio-2-ethoxycarbonyl-3-oxo-2-methylbutyl, **26**¹ or 4-acetylthio-2,2-dimethyl-3-oxobutyl, **27**¹), were prepared as outlined in Schemes 2-8. The coumarin or terephthalic acid and phosphate moieties are connected to each other through the *O*-hexyl oxime (**5**), *N*-arylsulfonamide-*O*-hexyl oxime (**9**), *O*-hexyl (**13**), hexylamide (**15, 22** and **23**), butylamide (**20, 24** and **25**) and methyl cyclohexylmethylamide (**17**) linkers. The 2,2-disubstituted 4-acylthio-3-oxobutyl group is an esterase- and thermolabile phosphate protecting group that enhances cellular uptake of the drug candidates. The enzymatic and nonenzymatic deprotection of 4-acetylthio-2-ethoxycarbonyl-3-oxo-2-methylbutyl and 4-acetylthio-2,2-dimethyl-3-oxobutyl group takes place by intramolecular cyclization to give the negatively charged phosphodiester and a substituted tetrahydrothiophenone (deprotection for **15** given as an example in Scheme 1).¹ Additionally, the 4,4-disubstituted dihydrothiophen-3(2H)-one byproduct is not markedly alkylating, confirmed by glutathione adduct experiments in our earlier studies.¹ If the enzymatic reaction becomes retarded, the thermolytic removal takes a place.²

4.2 A covalent calmodulin inhibitor as a tool to study cellular mechanisms of K-Ras driven stemness

Sunday Okutachi, Ganesh Babu Manoharan, Alexandros Kiriazis, Christina Laurini, Marie Catillon, Frank McCormick, Jari Yli-Kauhaluoma, Daniel Abankwa.

4.2.1 Manuscript 2: Summary

CaM is a universal calcium signal regulatory protein that is known to play a key role in cell cycle regulation (LaBaer et al., 1997). It is also highly expressed in malignant tissues and cancer cell lines (Berchtold and Villalobo, 2014). It was therefore pursued as a cancer drug target in the 1980s. Current data suggest that Ca²⁺/CaM is a K-Ras trafficking chaperone, able to facilitate the dynamic distribution of K-Ras in the cell (Agamasu et al., 2019, Grant et al., 2020b, Sperlich et al., 2016). Recent studies have implicated CaM in the promotion of K-Ras driven cancer stemness through the suppression of frizzled-8 mediated non-canonical Wnt signaling (Wang et al., 2015b). Indeed, our group previously showed that OphA disrupts the membrane organization of K-Ras4B in a CaM dependent manner and blocked the growth of cancer stem cell enriched spheroids (Najumudeen et al., 2016). However, the application of OphA as an inhibitor of CaM or a tool compound is limited by its high cellular toxicity (Chidley et al., 2016). Furthermore, studying CaM cell biology continues to be an interesting subject due to the vast implication of CaM in many cellular processes (Berchtold and Villalobo, 2014). However, the presence of 3 genes coding for this protein makes knockout and knockdown studies difficult. To this end, a major interest of this thesis is to develop novel CaM inhibitors that could be applied as potential chemical knock-down tools in cell biological studies.

In this study, we describe the identification and characterization of a novel covalent OphA-like CaM inhibitor named **Calmirasone1**. Calmirasone1 is a formyl-benzazulenone, which can be synthesized in a six-stepped reaction from guaiazulene. Initially, a small library of benzazulenones was synthesized and analyzed in cellular toxicity/viability assays, spheroid formation assays and a fluorescence polarization assay. Ras isoform specificity and on-target activity of the compounds in cells was determined using a newly developed BRET assay. Calmirasone1 showed a 4-fold higher affinity to CaM than OphA, it displayed a 7-fold faster reactivity with CaM in vitro whilst maintaining a similar K-Ras versus H-Ras cellular anticancer selectivity as OphA. Similarly, Calmirasone1 more selectively reduced the K-Ras BRET sensor signal than their H-Ras counterparts as did OphA but reached an over 38% K-Ras BRET inhibition within minutes as compared to the hours it took OphA. Furthermore, we showed that Calmirasone1 exhibited a clear

on-target activity by blocking the BRET between our K-Ras/CaM biosensors and confirmed its ability to selectively blocked K-Ras driven sphere formation whilst maintaining low unspecific cytotoxicity on the H-Ras mutated cancer cell lines. Likewise, in conformity with the central role of CaM in cell cycle regulation, we observed that Calmirasone1 induces a multipolar and an acentrosomal phenotype in HeLa cells. Conclusively, our results indicate that Calmirasone1 can serve as a novel tool compound for the elucidation of the cell biology of K-Ras/CaM associated cancer cell stemness characteristics.

4.2.2 Manuscript 2: Personal contributions of Sunday Okutachi

- Designed, performed and analysed the 3D spheroid assays as well as the 2D cell viability and toxicity assays
- Designed, performed and analysed all BRET assay data
- Performed all RT-qPCR experiments together with Marie Catillon and analysed all data
- Performed the DSS and composite drug activity score analysis
- Analysed and generated the ATARiS gene dependency profiling of the cell lines
- Generated and compiled all figures submitted for this manuscript
- Contributed to writing parts of the manuscript with guidance from Daniel Abankwa and Ganesh Manoharan

The personal contributions of all authors to the manuscript are listed in the *Authors' contributions* Section at the end of the corresponding manuscript.

Abstract

Word count: 219

Recently, the highly mutated oncoprotein K-Ras4B (hereafter K-Ras) was shown to drive cancer cell stemness in conjunction with calmodulin (CaM). We previously showed that the covalent CaM inhibitor ophiobolin A (OphA), can potently inhibit K-Ras stemness activity. However, OphA a fungus derived natural product, exhibits an unspecific, broad toxicity across all phyla. Here we identified a less toxic, functional analogue of OphA that can efficiently inactivate CaM by covalent inhibition. We analyzed a small series of benzazulenones, which bear some structural similarity to OphA and can be synthesized in only six steps. We identified the formyl aminobenzazulenone 1, here named Calmirasone1, as a novel and potent covalent CaM inhibitor. Calmirasone1 has a 4-fold increased affinity for CaM as compared to OphA and was active against K-Ras in cells within minutes, as compared to hours required by OphA. Calmirasone1 displayed a 2.5 - 4.5-fold higher selectivity for KRAS over BRAF mutant 3D spheroid growth than OphA, suggesting improved relative on-target activity. Importantly, Calmirasone1 has a 40 - 260-fold lower unspecific toxic effect on HRAS mutant cells, while it reaches almost 50% of the activity of novel K-RasG12C specific inhibitors in 3D spheroid assays. Our results suggest that Calmirasone1 can serve as a new tool compound to further investigate the cancer cell biology of the K-Ras and CaM associated stemness activities.

Contribution to the field

The interplay between the most frequently mutated oncogene KRAS and calmodulin (CaM) has been suggested as a drug target for cancer stem cells. While a critical role for KRAS in driving stemness is consistent with its high mutation rate, CaM was so far pursued as a cancer drug target because of its multiple roles during cell division. Both KRAS and CaM have been independently explored as drug targets for many years in the early 1990s. Recently, KRAS has gained significant interest again, which led to clinical stage covalent inhibitors targeting specifically the KRAS-G12C allele. It is currently not well understood how KRAS and CaM collaborate on the molecular cell biological level to drive stemness. We have here developed the first synthetic covalent CaM inhibitor, which has a significantly reduced toxicity as compared to its natural product counterpart Ophiobolin A. Our best inhibitor named Calmirasone1 now offers the opportunity to perform a 'chemical knockdown' of CaM, which is transcribed from three genes. This tool compound will allow to investigate the cellular interactions and activities of KRAS and CaM in driving cancer cell stemness.

Funding statement

A covalent CaM-inhibitor tool compound14 **1 Abstract**

15 Recently, the highly mutated oncoprotein K-Ras4B (hereafter K-Ras) was shown to drive cancer cell
16 stemness in conjunction with calmodulin (CaM). We previously showed that the covalent CaM
17 inhibitor ophiobolin A (OphA), can potently inhibit K-Ras stemness activity. However, OphA a fungus
18 derived natural product, exhibits an unspecific, broad toxicity across all phyla.

19 Here we identified a less toxic, functional analogue of OphA that can efficiently inactivate CaM by
20 covalent inhibition. We analyzed a small series of benzazulenones, which bear some structural
21 similarity to OphA and can be synthesized in only six steps. We identified the formyl
22 aminobenzazulenone **1**, here named Calmirasone1, as a novel and potent covalent CaM inhibitor.
23 Calmirasone1 has a 4-fold increased affinity for CaM as compared to OphA and was active against K-
24 Ras in cells within minutes, as compared to hours required by OphA. Calmirasone1 displayed a 2.5 –
25 4.5-fold higher selectivity for KRAS over BRAF mutant 3D spheroid growth than OphA, suggesting
26 improved relative on-target activity. Importantly, Calmirasone1 has a 40 – 260-fold lower unspecific
27 toxic effect on HRAS mutant cells, while it reaches almost 50% of the activity of novel K-RasG12C
28 specific inhibitors in 3D spheroid assays.

29 Our results suggest that Calmirasone1 can serve as a new tool compound to further investigate the
30 cancer cell biology of the K-Ras and CaM associated stemness activities.

31

32 **Keywords: K-Ras, calmodulin, covalent inhibitor, cancer stem cell (CSC), BRET**

A covalent CaM-inhibitor tool compound

33 **2 Introduction**

34 Calmodulin (CaM) is a small (17 kDa) dumbbell-shaped signaling adapter, with hundreds of protein
35 interactions and widespread functions in cellular signaling (Tidow and Nissen, 2013). Its two N- and
36 C-terminal lobes each contain two EF-hands that can coordinate altogether four Ca^{2+} ions. Ca^{2+} /CaM
37 classically recognizes with high, nanomolar affinity approximately 20-residue long peptides with bulky
38 hydrophobic and basic residues that become encased in the hydrophobic pocket formed by the two
39 lobes. This leads to a significant conformational change of CaM with loss of the central helical structure
40 (Tidow and Nissen, 2013). Non-canonical CaM binders typically possess a polybasic N- or C-terminus
41 with a single lipid-modification, which can bind to either or both of the hydrophobic pockets on the N-
42 and C-lobes (Grant et al., 2020b).

43 CaM has been pursued as a cancer drug target in the 1980s, due to its significant role in activating
44 CDKs in the cell cycle (Hait and Lazo, 1986). CaM levels increase during the cell cycle, peaking at
45 G2/M, with a drop-off thereafter (Berchtold and Villalobo, 2014). In addition, CaM seems to be
46 indirectly important for the activation of CDKs that are active in G1 (Tauler et al., 1998). CaM
47 distribution is furthermore tightly associated with cell division, as it co-distributes with major structures
48 of the mitotic machinery, such as the central spindle, centrosomes and the cleavage furrow (Li et al.,
49 1999; Yu et al., 2004). In line with this, CaM inhibitors have been demonstrated to block tumor growth,
50 such as for example in multiple myeloma cell line xenografts (Yokokura et al., 2014).

51 Several non-covalent CaM inhibitors have been developed including frequently used calmidazolium
52 (Sunagawa et al., 1999) and the highly water soluble and cell penetrating naphthalenesulfonamides,
53 such as W-7 (Hidaka et al., 1981; Sengupta et al., 2007). However, the latter can also inhibit CaM
54 targets, such as Ca^{2+} /CaM-dependent cyclic nucleotide phosphodiesterase at concentrations $> 100 \mu\text{M}$
55 (Itoh and Hidaka, 1984; Zimmer and Hofmann, 1984).

56 Ophiobolin A (OphA) is a potent, covalent CaM inhibitor (Leung et al., 1984). It is a naturally
57 occurring fungal 5-8-5 tricyclic sesterterpene metabolite with broad toxicity against plants, microbes
58 and cancer cells (Au et al., 2000). It forms an irreversible covalent adduct via C5, C21-dicarbonyl
59 functionalities after intermediate Schiff base formation with Lys 75 or Lys 77 and Lys 148 of CaM
60 (**Scheme S1**). Thus, OphA can react with CaM at a 2:1 ratio, similar to covalent phenothiazine
61 derivatives, which also react with the same lysines (Faust et al., 1987). Despite its potency against
62 CaM, OphA appears to have several other targets, such as phosphatidylethanolamine (Chidley et al.,
63 2016). Together with its broad toxicity across most phyla this suggests a problematic toxicity spectrum
64 of OphA.

65 We previously identified OphA as a K-Ras4B (hereafter K-Ras), but not H-Ras selective inhibitor
66 (Najumudeen et al., 2016). OphA disrupts membrane organization of K-Ras in a CaM dependent
67 manner and blocked the growth of cancer stem cell enriched spheroids derived from breast cancer cell
68 lines. Up to two K-Ras proteins can directly bind to the two lobes of Ca^{2+} /CaM (Agamasu et al.,
69 2019; Grant et al., 2020a). Interestingly, K-Ras has a higher affinity to the C-terminal lobe ($K_D = 0.5$
70 μM) than to the N-terminal lobe ($K_D = 4 \mu\text{M}$). Complementary to this, the C-terminal lobe of CaM
71 binds Ca^{2+} with higher affinity compared to the N-terminal lobe (Teleman et al., 1986). This affinity
72 constellation may underpin a Ca^{2+} -mediated K-Ras release mechanism. Binding of K-Ras is
73 nucleotide-independent, but dependent on the farnesylated C-terminus, while also geranylgeranylation
74 mediates binding albeit with an almost 10-fold lower affinity (Wu et al., 2011; Agamasu et al.,
75 2019; Grant et al., 2020a). In addition, basic residues of the hypervariable region of K-Ras may
76 contribute to the interaction, however, interaction with the prenyl moiety provides the core affinity
77 (Jang et al., 2019; Grant et al., 2020a). In contrast to these more recently established binding
78 determinants, a preference of CaM binding to GTP-K-Ras was previously observed (Villalonga et al.,
79 2001; Abraham et al., 2009).

A covalent CaM-inhibitor tool compound

80 Experimental data show that palmitoylated Ras isoforms do not interact with CaM (Villalonga et al.,
81 2001), probably because the palmitoyl-moiety would hinder binding to CaM sterically. Thus its client
82 selectivity could resemble that of PDE6D (PDE δ), a trafficking chaperone that is important for K-Ras
83 plasma membrane localization (Chandra et al., 2011). Indeed, evidence suggests that Ca²⁺/CaM can
84 act as a trafficking chaperone for K-Ras (Fivaz and Meyer, 2005; Grant et al., 2020a), which at high
85 concentration could sequester K-Ras from the membrane as it binds with a lower affinity ($K_D = 4 \mu\text{M}$)
86 to nanodiscs than to Ca²⁺/CaM (Gillette et al., 2015). Given that Ca²⁺/CaM has a different K-Ras
87 affinity, release mechanism, cellular distribution and probably client spectrum than PDE6D, it can be
88 expected that these proteins have overlapping, yet non-redundant chaperone functions. The interaction
89 of CaM with K-Ras is inhibited by phosphorylation of Ser181 in the C-terminus of K-Ras, while vice
90 versa CaM binding prevents phosphorylation (Alvarez-Moya et al., 2010). Intriguingly, the
91 phosphomimetic S181D has a reduced stemness potential (Wang et al., 2015b). Consistently, the
92 atypical PKC agonist prostratin reduced the growth in several murine tumor models, including
93 pancreatic cancer cell line derived xenografts (Wang et al., 2015b).
94 Thus, a novel rationale for the development of CaM inhibitors has emerged, which is tied to the K-Ras
95 dependent induction of cancer cell stemness. While this K-Ras and cancer stemness association may
96 rekindle CaM inhibitor drug development, further dissection of the molecular mechanism is hampered
97 by the fact that three transcribed copies of CaM genes exist (*CALM1-3*) in the human genome
98 (Toutenhoofd and Strehler, 2000). CaM cell biology is therefore difficult to dissect genetically.
99 Here we describe the identification of the formyl aminobenzazulenone **1**, later named Calmirasone1,
100 as a novel, covalent CaM inhibitor. The compound is synthetically readily accessible in a six-step
101 synthesis from commercially available guaiazulene. Its higher CaM affinity, fast K-Ras directed
102 cellular activity and > 40-fold reduced unspecific cell toxicity as compared to OphA allow utilization
103 of Calmirasone1 in acute cell biological experiments.

104 **3 Results**

105 **3.1 Phenotypic assessment of amino benzazulenones versus ophiobolin A**

106 OphA is a potent CaM inhibitor that covalently inactivates its target. We previously showed that it
107 selectively inhibits the functional membrane organization of oncogenic K-Ras. This enabled inhibition
108 of cancer stem cell features by an as yet not fully defined cellular mechanism (Najumudeen et al.,
109 2016). However, the broad toxicity of OphA limits its application (Chidley et al., 2016).
110 In order to identify a less toxic functional analogue of OphA for application in cell biological studies,
111 we chose the azulene-derived aromatic benzazulen-3-one scaffold, which is distantly related to the
112 nonaromatic 5-8-5 tricyclic ring framework of OphA. This choice was based only on the chemical
113 similarity and no additional compound-design or -screening efforts were made. We prepared two series
114 of synthetically easily accessible compounds, formylated and matching non-formylated
115 aminobenzazulenones, containing two or one electrophilic functionalities for covalent binding
116 (**Scheme 1**). The *ortho*-quinone methide electrophile is part of the ring structure and was shown to
117 react readily with primary amines in a nucleophilic aromatic substitution reaction (Kiriakis et al., 2017)
118 (**Data S1**), however, other nucleophiles could also react with it. In addition, formyl
119 aminobenzazulenones can undergo a typical Schiff base reaction with amines via their C1-formyl,
120 similar to OphA.
121 Given that toxicity was the major obstacle to overcome, we first characterized the effects of the
122 compounds in phenotypic assays. Clonogenic growth of breast cancer cell derived 3D tumor spheroids
123 under low adherent conditions, is a well-established assay for cancer stem cell properties (Dontu et al.,
124 2003). We were interested in compounds with high K-Ras selectivity in 3D spheroid assays, but low
125 general toxicity in 2D proliferation assays. Consistent with their Ras mutation status, MDA-MB-231

A covalent CaM-inhibitor tool compound

126 (K-RasG13D) and Hs 578T (H-RasG12D) spheroids were selectively sensitive to KRAS and HRAS
127 knockdown, respectively (**Figure S1 A-D**), as shown previously (Siddiqui et al., 2020).
128 Compounds showed varying potencies in 3D spheroids with IC_{50} values between 12 μ M and > 40 μ M
129 in MDA-MB-231, and 5.2 μ M and > 40 μ M in Hs 578T, as compared to 0.3 μ M and 1.8 μ M,
130 respectively, for OphA (**Table 1; Figure S1 E-H**). In order to have a more robust descriptor of the
131 compound effect on the clonogenic sphere forming ability of these cells, we used the drug sensitivity
132 score, DSS_3 , which is a normalized area under the dose-response curve value with superior accuracy
133 over IC_{50} determination (**Figure 1 A,B**) (Yadav et al., 2014). Thus, it became clear that some
134 compounds had a selectivity for the KRAS-dependent MDA-MB-231 spheroids that was similar to or
135 better than that of OphA.

136 Next we compared the general cytotoxicity (**Figure 1 C,D**) and anti-proliferative activity in cells grown
137 in 2D at 10 μ M compound concentration (**Figure S1 I,J**). Higher toxicities and anti-proliferative
138 effects with selectivity for MDA-MB-231 were generally observed for the formyl
139 aminobenzazulenones. However, none of the compounds tested at 10 μ M was as non-specifically toxic
140 as OphA at only 1 μ M against HRAS-dependent Hs 578T cells.

141 3.2 Several benzazulenones have a higher affinity to CaM than OphA

142 High affinity to the target typically reduces off-target toxicities (Bedard et al., 2020). We therefore
143 next determined the in vitro affinity of the 14 compounds to the intended target CaM using a
144 fluorescence polarization assay previously developed by us (Manoharan et al., 2019). This assay
145 measures the displacement of a fluorescein-labelled CaM-binding peptide, here derived from plasma
146 membrane calcium-ATPase (PMCA), from purchased CaM by the inhibitors (**Table 2; Figure S2**
147 **A,B**).

148 Compounds **2** and **3** showed the highest affinity (15-fold higher affinity than OphA) and **1** being third
149 best (4-fold higher affinity) after 24 h incubation. The fact that OphA had a significantly higher
150 cytotoxic- and antiproliferative activity (**Figure 1 C-D; Figure S1 I,J**), despite lower affinity than six
151 of the compounds, confirms its problematic off-target toxicity (Chidley et al., 2016).

152 Based on these in vitro and the phenotypic data, we calculated a customized **composite drug activity**
153 **score** to select compounds with most favorable properties in each series i.e. high overall activity in the
154 3D spheroid assay, high MDA-MB-231 KRAS-mutant cell line selectivity in 3D spheroid assays, low
155 relative 2D growth toxicity against Hs 578T cells relatively to MDA-MB-231 and high affinity (**Figure**
156 **S2 E,F**). Thus, we selected **1, 2, 3, 8, 9** and **11** for further analysis.

157 Of note, the binding affinity of OphA increased over several hours, consistent with the slow covalent
158 Schiff base bond formation and the additional pyrrole adduct formation (**Figure 2 A,B; Scheme S1**).
159 By contrast, most benzazulenones immediately showed high IC_{50} ranging from sub-micromolar to tens
160 of micromolar.

161 The potency and selectivity of covalent inhibitors are governed by two parameters namely K_i , the
162 affinity constant of initial non-covalent complex and k_2 , the rate of subsequent covalent bond-formation
163 (Singh et al., 2011). The latter cannot be too high to avoid non-specific reactivity. Analysis of the
164 reactivity of the top six compounds, revealed that formyl aminobenzazulenones had lower K_i as
165 compared to non-formylated compounds, suggesting that the formyl moiety decreases the non-covalent
166 affinity component (**Table 3; Figure S2 G,H**). This is consistent with the hydrophobic binding sites
167 on CaM. However, k_2 increased for **1** and **2**, as well as **8** and **9**, with both **2** and **9** having a covalent
168 bond rate constant as high as that of OphA, which also showed an intermediate K_i value.

169 3.3 Cellular BRET experiments confirm K-Ras selectivity of top compound 1

A covalent CaM-inhibitor tool compound

170 Ras proteins are tightly packed into proteo-lipid membrane signaling complexes called nanoclusters
171 (Abankwa et al., 2007). Fluorescent tagging of Ras proteins with a pair of FRET-enabling fluorophores
172 thus leads to the emergence of nanoclustering-dependent FRET. Loss of this FRET signal reports
173 however not only on the loss of nanoclustering, but also on any upstream processes, i.e. proper Ras
174 plasma membrane trafficking or lipid modifications (Kohnke et al., 2012).

175 Here we established an analogous nanoclustering-BRET assay by tagging RasG12V proteins with
176 Rluc8, enabling donor emission, and GFP2 as acceptor. As expected, treatment with mevastatin, which
177 blocks prenyl-synthesis, reduced nanoclustering-BRET of both Ras isoforms fairly indiscriminately,
178 while treatment with a farnesyl transferase inhibitor (FTI-277) selectively (1.4-fold) decreased H-Ras
179 nanoclustering-BRET (**Figure 3 A,B**), due to the alternative prenylation of K-Ras, as described before
180 (Kohnke et al., 2012).

181 Inhibition of the trafficking chaperone PDE6D, which facilitates plasma membrane trafficking in
182 particular of K-Ras, decreases selectively K-Ras nanoclustering-FRET (Siddiqui et al., 2020). In
183 agreement with CaM acting as a trafficking chaperone that can likewise promote forward trafficking
184 to the plasma membrane, we observed a K-Ras selective reduction of nanoclustering-BRET after CaM
185 inhibition with calmidazolium (1.5-fold) and OphA (1.2-fold). The atypical PKC agonist prostratin,
186 which would stimulate K-Ras-Ser181 phosphorylation and thus block CaM binding, had a similar
187 selectivity (1.5-fold) as the CaM inhibitors.

188 We then tested the top six compounds in this assay in order to directly assess their in cellulo K-Ras
189 selectivity. While most compounds appeared to show some level of K-Ras selectivity (all < 1.3-fold)
190 when compared at 20 μ M and 24 h exposure (**Figure 3 A,B**), testing over a wider concentration range
191 revealed distinct potencies and selectivities (**Figure S3 A,B**). We employed the DSS analysis adapted
192 to BRET-data (BRET-DSS₃) to quantify these activities (**Figure 3 C**). While again overall BRET-
193 activity was highest for OphA, K-Ras-selectivity was highest for **1**. All other compounds had lower
194 and non-significant selectivities. By doing a BRET donor saturation titration analysis, we further
195 confirmed that **1** has a similar K-Ras vs. H-Ras selectivity as OphA (**Figure 3 D,E**; **Figure S3 C-F**).
196 Compound **1** affinity to CaM changes less over time than that of OphA, suggesting it assumes its full
197 activity faster (**Figure 2**), which could be advantageous if true also in cellular applications. We
198 therefore tested this property in cells using the K-Ras BRET biosensor. In order to see clear effects at
199 short exposure times, all compound concentrations were increased. OphA showed no significant BRET
200 change during the 2 h treatment timeframe, consistent with the significant time it requires for high
201 affinity binding (**Figure 2**). Likewise, mevastatin did not cause any reduction in the BRET signal, as
202 it has to block metabolic pathways for farnesyl- and geranylgeranyl-pyrophosphate synthesis and
203 therefore acts slowly after protein turnover. In agreement with the in vitro data, **1** showed a 38%
204 reduction in BRET signal within 10 minutes of treatment (**Figure 3 F**). It was therefore even more
205 active acutely in cells than the non-covalent CaM inhibitors trifluoperazine ($K_d = 1.35 \mu$ M) or
206 calmidazolium ($K_d = 13.5$ nM) (Manoharan et al., 2019).

207 3.4 BRET experiments confirm K-Ras/ CaM disrupting on-target activity in cells

208 Previously a preference of CaM binding to active, GTP-K-Ras was observed (Villalonga et al.,
209 2001; Abraham et al., 2009). In agreement with these data, we observed in cells a higher BRET of N-
210 terminally Rluc8-tagged K-RasG12V with GFP2-CaM, than of non-oncogenic K-Ras (**Figure 4 A**;
211 **Figure S4**). Likewise higher BRET levels were confirmed with three additional oncogenic mutants of
212 K-Ras (**Figure 4 B**; **Figure S4 A,B**). Furthermore, in line with previous reports (Villalonga et al.,
213 2001), K-RasG12V (BRET_{max} = 0.35 \pm 0.02) displayed a significantly ($p = 0.001$, unpaired t test) higher
214 cellular BRET ratio with GFP2-CaM than H-RasG12V did (BRET_{max} = 0.20 \pm 0.02), which remained
215 at or below control levels (**Figure 4 C**; **Figure S4**). This could explain the preferential effect on K-Ras
216 nanoclustering-BRET by CaM inhibitors (**Figure 3**).

A covalent CaM-inhibitor tool compound

217 In order to have a high dynamic range of the BRET-signal, we used the Rluc8-K-RasG12V/ GFP2-
218 CaM BRET pair to directly assess the effect of modulators of the K-Ras/ CaM interaction. Both CaM
219 inhibitor calmidazolium and OphA significantly reduced the BRET signal. Surprisingly, prostratin did
220 not have an effect at the tested concentration (**Figure 4 D**).

221 To further delineate the structural requirements for the on-target, K-RasG12V/ CaM disrupting
222 activity, we tested formyl aminobenzazulenone **1** in comparison to the closely related, but less active
223 aminobenzazulenone derivative **8**, which lacks the C1-formyl group. Compound **1** ($IC_{50} = 31 \pm 2 \mu M$)
224 was significantly more active than **8** ($IC_{50} = 70 \pm 11 \mu M$; $p = 0.03$), also when tested over a wider
225 concentration range (**Figure 4 E**). Yet, OphA remained the most effective compound in this cellular
226 assay after a 24 h long exposure ($IC_{50} = 12 \pm 2 \mu M$).

227 3.5 Dependence of the activity of top compound 1 on lysines 75, 77 and 148 of CaM

228 We previously showed that the K-Ras directed effect of OphA is abolished if a lysine-mutant of CaM
229 is expressed to rescue the knockdown of endogenous CaM (Najumudeen et al., 2016). In this mutant
230 CaM (mutCaM) lysines 75, 77 and 148 were replaced by glutamine, i.e. those residues that were
231 reported to be modified by OphA (Kong Au and Chow Leung, 1998). To assess the dependence of
232 compound **1** binding to CaM on these lysine residues, we again employed a fluorescence polarization
233 assay using in house purified, His-tagged CaM or mutCaM. Both variants bound to the fluorescein-
234 labelled peptide of Ca^{2+} /calmodulin dependent kinase II (CaMKII) (Manoharan et al., 2019). As
235 observed before (**Figure 2**), the affinity of OphA to wild-type (wt) CaM increased over several hours,
236 while no binding was observed to mutCaM (**Figure 5 A**; **Figure S5 A,B**), as reported previously
237 (Najumudeen et al., 2016; Manoharan et al., 2019). By contrast, compound **1** also displayed binding to
238 mutCaM, however, as compared to wt CaM, the affinity did not increase over time (**Figure 5 B**; **Figure**
239 **S5 E,F**). This was different for the non-formylated counterpart **8**, which showed the same binding
240 affinity for wt CaM and mutCaM over time (**Figure 5 C**; **Figure S5 E,F**). The comparison of the
241 activities of all three compounds suggests that the K75Q, K77Q, and K148Q mutations in the mutCaM
242 has rendered CaM partially insensitive to **1** and **8** binding. It furthermore shows that the lysine-
243 dependent increase in affinity over time of compound **1** depends on the C1-formyl, which could form
244 a Schiff base bond in a slow reaction.

245 3.6 Activity in cell proliferation assays correlates with the K-Ras dependence of cancer cell 246 lines

247 Unspecific, broad toxicity against KRAS (MDA-MB-231, MIA PaCa-2) and HRAS mutant (Hs 578T,
248 T24) cancer cell lines, as well as HEK293-EBNA cells is a major issue of OphA (**Figure 6 A**). This
249 broad toxicity appears to greatly contribute to the high 'anti-cancer cell activity' that is observed with
250 this compound, and clearly contrasts to the KRAS mutant cancer cell line selectivity seen with
251 calmidazolium and **1** (**Figure 6 B**; **Figure S6 A-E**). Of note, the latter has a background activity against
252 HRAS mutant cancer cells that was as low as that of the covalent K-RasG12C inhibitor AMG-510.

253 When compounds were compared in 3D spheroid growth assays, the significant potency difference
254 between clinical compounds and **1** became however more obvious than in 2D assays. Both AMG-510
255 and vemurafenib selectively and potently abolished growth of the K-RasG12C- and BRAF-V600E-
256 mutant cancer cell 3D spheroids, respectively, with basically no activity against other cancer cell
257 spheroids (**Figure 6 C**; **Figure S6 F-I**). Compound **1** had a visibly lower activity, yet the activity
258 profile seemed to correlate with the KRAS dependence of the cancer cell lines (**Figure 6 C,D**). Again,
259 OphA appeared highly potent, yet clearly at the cost of its broad toxicity (**Figure 6 A,C**). These data
260 are in line with a much improved on target activity of **1** as compared to OphA.

261 3.7 The best tool compound 1 can be utilized in cell biological experiments

A covalent CaM-inhibitor tool compound

262 Given the significantly reduced unspecific toxicity of **1** as compared to OphA, we tested its application
263 in cell biological experiments. CaM dynamically localizes to centrosomes, spindle and other structures
264 during mitosis, and its inhibition is known to affect proper cleavage furrow formation, which can lead
265 to multipolarity (Yu et al., 2004; Wu et al., 2010).
266 In order to track this phenotype and the CaM distribution, we transfected HeLa cells with a mCherry-
267 CaM construct, which primarily localized to centrosomes in mitotic cells (**Figure 7 A**). When these
268 cells were synchronized and treated with the potent, non-covalent CaM inhibitor calmidazolium, an
269 increased fraction of multipolar cells with multiple mCherry-CaM-positive centrosomes was observed.
270 As expected from the faster in cell activity observed in BRET experiments (**Figure 3 F**), this phenotype
271 was significantly pronounced with **1** (**Figure 7 B**), confirming its utility in cell biological experiments.
272 Finally, we named compound **1**, the best performing tool compound, **Calmirasone1**.

273 **4 Discussion**

274 We have here identified compound **1**, which we named **Calmirasone1**, a synthetically well accessible,
275 high affinity covalent CaM inhibitor with fast cellular K-Ras selectivity and significantly lower toxicity
276 than the natural product counterpart OphA. While the current potency and properties of **Calmirasone1**
277 do not fit for a compound with future medical applications, our data support its intended utility as a
278 tool compound in cell biological applications to study CaM dependent cellular processes. Such tool
279 compounds are important also for drug development, as they can foreshadow some on-target issues
280 and reveal crucial mechanistic features of actual drug candidates.

281 Several of our compounds bound to CaM with submicromolar affinity, with **Calmirasone1** binding 4-
282 times better than OphA. Comparison of **Calmirasone1** and **8** affinities with purified wt and mutant
283 CaM suggests that the affinity binding component that remained constant over time was independent
284 of the C1-formyl (**Figure 5**). This immediate high affinity could have been of non-covalent or actually
285 also of covalent nature. Given that a second reactive group with covalent binding potential (ortho
286 quinone-methide, *o*-QM) is present in both **Calmirasone1** and **8**, it is possible that this electrophile
287 mediates additional covalent binding to lysine residues other than those three mutated lysines in
288 mutCaM (**Data S1**), or alternatively cysteines. However, nucleophilic cysteines are not present in the
289 studied CaM variants. Based on previous synthetic studies the *o*-QM reactivity towards nucleophiles
290 (amine or thiol) can be very fast (within minutes) and proceeds via a nucleophilic aromatic substitution
291 (S_NAr -type) reaction (Kiriazis et al., 2017). We currently lack evidence, whether this second
292 electrophile is also engaged covalently.

293 Our rate analysis (**Table 3**) shows that the compound with the highest second order rate constant was
294 **2**, followed by **3**. However, as our cellular BRET-data in **Figure 3 C** indicate, this increased reactivity
295 appears to come at the cost of selectivity. We see a maximal selectivity for K-RasG12V vs. H-
296 RasG12V for **1**, which has intermediate parameters, in agreement with a balance between sufficient
297 affinity and a moderate reactivity.

298 We speculate that the formyl-independent binding component significantly improves the unspecific
299 toxicity of compounds **Calmirasone1** and **8** (**Figure 1 C,D**). However, the major, slower affinity
300 increase stems from the C1-formyl and depends on mutated lysines 75,77 and 148. This is consistent
301 with the formyl as a hard electrophile reacting with lysine as a hard nucleophile. The typically slow
302 Schiff base formation may therefore explain the slow increase in the effective affinity (**Figure 5 B**).
303 The formyl substituent is furthermore beneficial, as it lowers the relatively high clogP, thus potentially
304 increasing water solubility of these not very drug-like molecules.

305 Currently, the structural basis for CaM inhibition by OphA is not known. However, similar to other
306 non-covalent inhibitors, such as trifluoperazine, the conformational dynamics of CaM may change
307 dramatically upon inhibitor binding, collapsing the original dumbbell shaped molecule into a compact
308 globular structure (Vandonselaar et al., 1994). We speculate that covalent inhibitors, such as OphA and

A covalent CaM-inhibitor tool compound

309 the here tested compounds would have a similar effect on the conformation and therefore activity of
310 CaM to bind its canonical and non-canonical clients, such as K-Ras.
311 The Ras nanoclustering-dependent BRET-assay that we used before successfully in the FRET-format
312 to assess the Ras-selectivity close to the mechanistic target K-Ras (Najumudeen et al., 2016; Posada et
313 al., 2016), is sensitive to disruption of Ras membrane anchorage and correct plasma membrane
314 trafficking. CaM was recently established as a K-Ras trafficking chaperone which can essentially act
315 as a solubilizing factor to shield the farnesyl tail from the aqueous environment of the cytoplasm (Grant
316 et al., 2020a). Therefore, the drop in K-Ras nanoclustering-BRET with CaM inhibitors is consistent
317 with CaM being a trafficking chaperone for K-Ras (Grant et al., 2020b).
318 We have previously demonstrated similar changes in membrane anchorage of K-Ras with the inhibition
319 of PDE6D, another prominent trafficking chaperone of K-Ras (Siddiqui et al., 2020). For PDE6D,
320 clients such as H-Ras that are in addition palmitoylated, cannot bind as long as they are palmitoylated
321 (Chandra et al., 2011; Dharmiah et al., 2016). This establishes an effective K-Ras over H-Ras
322 selectivity for PDE6D inhibition induced cell growth effects (Siddiqui et al., 2020). Grant et al. recently
323 derived singly lipidated polybasic termini of proteins as non-canonical CaM interaction sequences
324 (Grant et al., 2020a). Consistently, K-Ras but not H-Ras or N-Ras bind to CaM (Villalonga et al.,
325 2001). It can be speculated that any additional palmitoylation would sterically hinder access to CaM,
326 making palmitoylated Ras isoforms clients only if they are in their non-palmitoylated state (Agamasu
327 et al., 2019). This would explain why the potent CaM inhibitor calmidazolium decreased the BRET-
328 signal of H-Ras, albeit to a lesser extent than that of K-Ras (**Figure 3 A,B**).
329 The highly potent calmidazolium, as well as the covalent inhibitors OphA and **Calmirasone1**
330 significantly disrupted K-Ras/ CaM-BRET in cells. By contrast, the PKC agonist prostratin had no
331 effect on K-Ras/ CaM-BRET, but on K-RasG12V nanoclustering BRET. It may therefore be that
332 prostratin exerts its K-Ras selectivity by a different mechanistic route than inhibition of K-Ras/ CaM
333 interaction. Interestingly, prostratin had almost no effect on cell growth in 3D spheroid assays (**Figure**
334 **6 C**).
335 Clonogenic 3D spheroid growth depends on stemness associated asymmetric and symmetric division
336 processes of cancer cells with stemness traits (Cicalese et al., 2009). Accordingly, **Calmirasone1**
337 demonstrates an efficacy against 3D spheroid growth that correlates with the KRAS-dependence of the
338 tested cell lines. In this regard it is noteworthy that the DSS₃-potency of **Calmirasone1** reaches already
339 approximately 50% of AMG-510, the K-RasG12C inhibitor that is currently being evaluated in the
340 clinic (Hong et al., 2020). However, a much larger number of cell lines would have to be tested to
341 demonstrate a correlation between compound activity and anticipated K-Ras/ CaM targeting
342 mechanism. For instance, both cell lines that were employed here also carry mutations in BRAF
343 (MDA-MB-231) or in TP53 (both MDA-MB-231 and Hs578T). For both B-Raf and p53 connections
344 to CaM signaling have been reported (Ren et al., 2008; Taylor et al., 2020), hence the cell killing activity
345 may relate to multiple pathways that are affected downstream of CaM.
346 In addition, we could demonstrate the benefits of using **Calmirasone1** as a tool compound in cell
347 biological experiments, which are not possible with OphA due to its high toxicity. We observed the
348 induction of multipolar cells by CaM inhibitor treatment. Inhibition of CaM affects multiple processes
349 during cell division, notably cleavage furrow formation (Yu et al., 2004). While failure of cytokinesis
350 can lead to chromosomal instability and therefore a hallmark of cancer cells, the exact nature of the
351 multipolar phenotype and additional effects could also play a role in the ultimately cell growth
352 inhibiting effect of CaM inhibition (Wu et al., 2010). Interestingly, a different compound that induces
353 multipolar acentrosomal spindles was found to selectively kill tumor cells (Wang et al., 2015a). In our
354 cell biological experiments **Calmirasone1** ($K_d = 0.87 \pm 0.02 \mu\text{M}$) can be considered more effective
355 than non-covalent calmidazolium ($K_d = 13.5 \text{ nM}$) (**Figures 3 F and 7 B**). While **Calmirasone1** was
356 used at 2.5-fold higher concentration, the 64-fold affinity difference between these two compounds
357 suggests a > 25-fold higher effectivity of **Calmirasone1**. Therefore, **Calmirasone1** can be used to

A covalent CaM-inhibitor tool compound

358 acutely (within 30 – 60 minutes) perform a chemical knock-down of CaM in cells in a more efficient
 359 manner than with the most potent non-covalent inhibitor calmidazolium.
 360 Covalent inhibitors have experienced a renaissance in the past few years (Singh et al., 2011). Our novel
 361 covalent CaM inhibitor **Calmirasone1** will add to the arsenal of covalent tool compounds to study in
 362 particular the cell biology of K-Ras/ CaM driven stemness processes.

363 5 Methods

364 5.1 Compound synthesis

365 Synthesis of chemical compounds and their analytical information are given in **Supplementary**
 366 **Material Data S1**.

367 5.2 Expression constructs and siRNA

368 Most expression constructs described in the study were produced by multi-site gateway cloning as
 369 described (Wall et al., 2014) (**SI Table 1**). For plasmids used in BRET assay, three entry clones, with
 370 compatible LR recombination sites, encoding the CMV promoter, Rluc8 or GFP2 tag and the gene of
 371 interest were recombined with a destination vector, pDest-305 or pDest-312 using Gateway LR
 372 Clonase II enzyme mix (cat. no. 11791020, ThermoFisher Scientific). The reaction mix was
 373 transformed into *ccdB* sensitive *E. coli* strain DH10B (cat. no. EC0113, ThermoFisher Scientific) and
 374 positive clones were selected using ampicillin. pDest527-His-wtCaM and pDest527-His-mutCaM
 375 were produced from the LR reaction between pDest-527 vector with either entry clone pDONR221-
 376 wtCaM or pDONR221-mutCaM. The N-terminally GFP2-tagged CaM plasmid, pDest-CMV-GFP2-
 377 CaM was cloned at Genecust (France) and amplified in *E. coli* CopyCutter EPI-400 strain (cat. no.
 378 C400CH10, Lucigen) according to the manufacturer's instruction. All the plasmids were verified by
 379 sequencing. Expression and localization of the Ras and CaM fusion proteins were confirmed by
 380 confocal microscopy (**SI Figure 7**). Protein sequences of all expression constructs are given in the
 381 Supplementary Material section. pmCherry-wtCaM was previously described (Manoharan et al.,
 382 2019).

383 Knockdown of CALM1 was done using a master mix of multiple siRNA against the CALM1 transcript
 384 (QIAGEN Hs_CALM1, siRNAs: SI00092925 (CALM1_4), SI02224215 (CALM1_5), SI02224222
 385 (CALM1_6) and SI03649268 (CALM1_8)). For knockdown of specific Ras isoforms, we used for
 386 KRAS (K-Ras4A + K-Rras4B- L-005069-00) and HRAS (L-004142-00) Dharmacon On-Target plus
 387 siRNA SMARTpools. Scrambled siRNA control was from QIAGEN (cat. no. 102276).

388 5.3 Commercial chemical inhibitors

389 Fluorescein-labeled CaMKII and PMCA peptide were from Pepmic, China, and Genscript, USA
 390 respectively (Manoharan et al., 2019). DMSO was from PanReac-AppliChem (cat. no. A3672, ITW
 391 Reagents). Sources of the inhibitors used in the study are listed below.

Compound	Source	Catalogue Number
ophiobolin A	Santa Cruz	sc-202266
mevastatin	Alfa Aesar	J61357
FTI-277	BioVision	2874
prostratin	Sigma-Aldrich	P0077
calmidazolium	Santa Cruz	sc-201494
AMG-510	MedChem Express	HY-114277
vemurafenib	Selleckchem	S1267
trifluoperazine	Cayman	15068

A covalent CaM-inhibitor tool compound

benzethonium chloride	Sigma-Aldrich	53751

392

393 **5.4 RT-qPCR analysis of gene transcript knockdown**

394 MDA-MB-231 and Hs 578T cells were seeded in 12-well plates and transfected with indicated amounts
 395 of siRNAs. Where required, siRNA was transfected into cells using Lipofectamine RNAiMAX (cat.
 396 no. 13778075, ThermoFisher Scientific) reagent according to manufacturer's instruction. After 24 h of
 397 transfection, total RNA was isolated using NucleoZol (cat. no. 7040404, Macherey-Nagel) according
 398 to the manufacturer protocol. Reverse transcription was performed with 1 µg of total RNA using
 399 SuperScript III Reverse Transcriptase (cat. no. 18080093, ThermoFisher Scientific). The knockdowns
 400 of KRAS, HRAS and CALM1 gene transcripts were analyzed by real-time qPCR using SsoAdvanced
 401 Universal SYBR Green Supermix (cat. no. 1725274, BIO-RAD), on the CFX-connect real-time PCR
 402 instrument (BIO-RAD). The transcripts were selectively amplified using specific primers producing
 403 amplicons for total KRAS (both KRAS4A and KRAS4B), HRAS and CALM1. The gene transcript
 404 ACTB encoding for β-actin was used as reference. The following primers were used (Tsai et al., 2015):
 405 for total KRAS, forward 5'- tacagtccaatgaggacca-3', reverse 5'- tcctgagcctgtttgtct-3' (amplicon
 406 206 bp); for HRAS, forward 5'- ctgacctccagctgatcca-3', reverse 5'- tggcaaacacacacaggaag-3'
 407 (amplicon 196 bp); For ACTB, forward 5'- ggggtgttgaaggtctcaaa-3'; reverse 5'- ggcatcctcaccctgaagta-
 408 3' (amplicon 203 bp); For CALM1, forward 5'- gctcgcaccatggctgat-3', reverse 5'-
 409 tgttggttctgaccagtg-3' (amplicon 144 bp).

410 **5.5 3D Spheroid Assays**

411 3D spheroid formation assays were performed in 96-well low-attachment, suspension culture plates
 412 (cat. no. 655185, Cellstar, Greiner Bio-One) under serum free condition. About 1000 (MDA-MB-231,
 413 NCI-H358 and MIA PaCa-2) or 2500 (Hs 578T) cells per well were seeded in 50 µL of either RPMI
 414 medium (cat. no. 52400-025, Gibco, ThermoFisher Scientific) (MDA-MB-231, A375 and NCI-H358)
 415 or DMEM (cat. no. 41965-039, Gibco, ThermoFisher Scientific) (Hs 578T and MIA PaCa-2),
 416 containing 0.5% MethoCult (cat. no. SF H4636, Stemcell technologies), 1x B27 (cat. no. 17504044,
 417 Gibco, ThermoFisher Scientific), 25 ng/mL EGF (cat. no. E9644, Sigma-Aldrich) and 25 ng/mL FGF
 418 (cat. no. RP-8628, ThermoFisher Scientific). Cells were cultured for 3 days and then treated with
 419 compounds or vehicle control (DMSO 0.1% v/v in growth medium) for another 3 days. The cells were
 420 supplemented with fresh growth medium on the third day together with the drug treatment. For
 421 knockdown experiments, cells were seeded in 12-well plates and treated with either 50 nM scrambled
 422 siRNA (cat. no. 1022076, QIAGEN) or indicated concentrations of siRNAs. Next day, cells were
 423 collected by trypsinization and re-plated into 96-well plates for 3D spheroid suspension culture.
 424 Spheroid formation efficiency was analyzed by alamarBlue assay reagent (cat. no. DAL1100,
 425 ThermoFisher Scientific). A 10% final volume of alamarBlue reagent was added to each well of the
 426 plate and incubated for 4 h at 37 °C. Then the fluorescence intensity was measured using the FLUOstar
 427 OPTIMA plate reader (BMG Labtech, Germany) with an excitation wavelength of 560 ± 5 nm and
 428 emission wavelength of 590 ± 5 nm. The obtained fluorescence intensity data were normalized to
 429 vehicle control corresponding to 100% sphere formation and the signal after 100 µM benzethonium
 430 chloride treatment, which killed all cells (i.e. maximum inhibition of sphere formation).

431 **5.6 Drug sensitivity score (DSS) analysis**

432 To quantitatively profile the drug sensitivity with a more robust parameter than the IC₅₀ or EC₅₀ values,
 433 the drug sensitivity score (DSS) analysis was employed. DSS values are essentially normalized area
 434 under the curve (AUC) measures of dose-response inhibition data (Yadav et al., 2014). Drug response

11

A covalent CaM-inhibitor tool compound

435 data files (in Excel) ready for online analysis were prepared according to the example file obtained
 436 from the DSS pipeline website, called Breeze (<https://breeze.fimm.fi/>) (Potdar et al., 2020). Either raw
 437 fluorescence intensity measurements or normalized % inhibition data (for BRET assay analysis) were
 438 uploaded.

439 The output file provides several drug sensitivity measures including EC₅₀ and AUC. We plotted the
 440 DSS₃ value (Yadav et al., 2014), which was calculated as

$$441 \quad DSS_3 = DSS_2 \frac{x_2 - x_1}{C_{max} - C_{min}}$$

442 Where DSS₂ is given by the equation $DSS_2 = \frac{DSS_1}{\log a}$

443 and DSS₁ is given by the equation $DSS_1 = \frac{AUC - t(x_2 - x_1)}{(100 - t)(C_{max} - C_{min})}$

444 DSS₃ was employed to emphasize drugs that obtain their response area over a relatively wide dose
 445 window, as compared to drugs that show increased response only at the higher end of the concentration
 446 range. After logistic fitting of the dose-response inhibition data, the area under the curve (AUC) was
 447 determined as exact solution. A 10% minimal activity threshold (t) was set. The maximum (C_{max}) and
 448 minimum (C_{min}) concentrations were used for screening of the inhibitors, with C_{max} = x₂ and x₁
 449 concentration with minimal activity t. The parameter a is the value of the top asymptote, which can be
 450 different from 100% inhibition as obtained from 100 μM benzethonium chloride treatment.

451 5.7 2D cell toxicity and viability assays

452 Hs 578T and MDA-MB-23 cells cultured in complete DMEM and RPMI medium (i.e supplemented
 453 with 10% FBS (cat. no. 10270-098, Gibco, ThermoFisher Scientific), 2 mM L-glutamine (cat. no.
 454 25030-024, ThermoFisher Scientific)), respectively, were plated onto 96-well F-bottom cell culture
 455 plates (cat. no. 655180, Cellstar, Greiner Bio-One) at a density of 1000 cells (MDA-MB-231, MIA-
 456 PaCa-2, T24 and HEK293-EBNA) and 2500 cells (Hs 578T) per well grown for 24 h. Freshly thawed
 457 aliquots of test compounds were then added at indicated concentrations. DMSO 0.2% v/v in growth
 458 medium was used as vehicle control. Plates were further incubated for 72 h. The cell viability and cell
 459 toxicity effects were analyzed by alamarBlue and CellTox Green (cat. no. G8743, Promega) assays,
 460 respectively. A 10% final volume of alamarBlue reagent was added to each well of the plate and
 461 incubated for 4 h at 37 °C. Then the fluorescence intensity was measured using the FLUOstar OPTIMA
 462 plate reader (BMG Labtech) with an excitation wavelength of 560 ± 5 nm and emission wavelength of
 463 590 ± 5 nm. The obtained fluorescence intensity data were normalized to vehicle control (100%
 464 viability).

465 For the CellTox Green assay, 100 μL of 2x CellTox Green reagent was added to each well of 96-well
 466 plate containing 100 μL of medium. The plate was protected from light and incubated for 15 min at 37
 467 °C, then orbitally shaken for 1 min at 700 – 900 rpm. The fluorescence intensity was measured using
 468 the Clariostar plate reader (BMG Labtech) with an excitation wavelength of 485 ± 4 nm and emission
 469 wavelength of 530 ± 4 nm. The obtained fluorescence intensity data were normalized to vehicle control
 470 (0% toxicity).

471 5.8 Protein purification

472 Our numbering of CaM follows (Kong Au and Chow Leung, 1998) with Ala being the first amino acid
 473 in human CaM, as the N-terminal methionine of CaM is removed in most organisms (Halling et al.,
 474 2016). His-wtCaM and His-mutCaM were expressed in *E. coli* BL21 Star (DE3)pLysS (cat. no.
 475 C602003, ThermoFisher Scientific). pDest527-His-wtCaM and pDest527-His-mutCaM plasmids
 476 encoding wild-type human CaM and CaM with K75Q, K77Q and K148Q mutations respectively, were
 477 transformed into *E. coli* BL21 Star (DE3)pLysS and grown in Luria Broth medium supplemented with

A covalent CaM-inhibitor tool compound

478 ampicillin (100 µg/mL). At A_{600} of 0.6 – 0.8, the culture was induced with 0.5 mM of isopropyl β-D-
 479 thiogalactopyranoside and expressed for 16 h at 25 °C. Cells were collected by centrifugation and
 480 incubated on ice for 30 min. The cell suspension was sonicated in lysis buffer (20 mM HEPES, pH 7.6,
 481 150 mM NaCl, 5 mM MgCl₂, 0.5 mg/mL lysozyme, and DNase I). The lysates were clarified by
 482 centrifugation at 18000 g for 30 min at 4 °C. The soluble fractions were subjected to protein purification.
 483 The His-tagged proteins were purified on HisTrap™ HP Prepacked Columns (GE Healthcare) using
 484 the chromatography system ÄKTAprime plus (GE Healthcare). The columns were equilibrated in a
 485 buffer composed of 50 mM Tris HCl, pH 7.5, 150 mM NaCl, and 35 mM imidazole, and the His-
 486 tagged proteins were eluted in elution buffer containing 250 mM of imidazole. The eluted fractions
 487 were dialyzed for 16 h at 4 °C in buffer composed of 50 mM Tris HCl, pH 7.5, 150 mM NaCl, and 2
 488 mM CaCl₂. Protein concentration was measured using NanoDrop 2000c Spectrophotometer
 489 (ThermoFisher Scientific) and purified proteins were analyzed on a 4 – 12% NuPAGE gel (cat. no.
 490 NP0321, ThermoFisherScientific) (SI Figure 8).

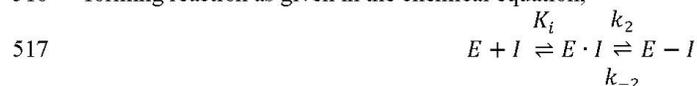

491 5.9 Fluorescence polarization assay

492 Fluorescence polarization (FP) assays were performed as described (Manoharan et al., 2019). The IC₅₀
 493 of compounds were determined in a binding/ displacement assay using fluorescein-labelled PMCA
 494 peptide (derived from plasma membrane Ca²⁺ transporting ATPase, a CaM binding protein) as the
 495 probe and recombinant bovine calmodulin (cat. no. 208690, Merck), which has an amino acid sequence
 496 identical to the human isoform. The F-CaMKII peptide was used at 5 nM concentration with 50 nM of
 497 His-tagged wt and mutCaM. FP assays were carried out in black low volume round bottom 384-well
 498 plate (cat. no. 4514, Corning) with a reaction volume of 20 µL. Compounds were three-fold diluted in
 499 assay buffer (20 mM Tris Cl pH 7.5, 50 mM NaCl, 1 mM CaCl₂ and 0.005% Tween 20) and a complex
 500 of 100 nM CaM and 10 nM F-PMCA peptide was added. The FP signals were recorded on the
 501 Clariostar (BMG labtech) plate reader with excitation at 482 ± 8 nm and emission at 530 ± 20 nm at
 502 25 °C, after 30 min to 60 min interval for up to 5 h. Then the plate was incubated overnight at 4 °C and
 503 the next day final readings were taken after a total of 24 h incubation. The fluorescence anisotropy was
 504 calculated and plotted against the logarithm of the compound concentration and fit to log inhibitor vs.
 505 response – variable slope (four parameters) equation in Prism (GraphPad). The IC₅₀ of the inhibitor
 506 was converted into K_d as described in (Sinijarv et al., 2017) using the equation,

$$507 \quad K_d = \frac{[I]_{50}}{1 + \frac{[P]_{50}}{K_{D,probe}} + \frac{[E]_0}{K_{D,probe}}}$$

508 where $[I]_{50}$ is the concentration of free inhibitor at 50% displacement, given as $[I]_{50} = IC_{50} - [EI]_{50}$,
 509 where $[EI]_{50}$ is the concentration of CaM:inhibitor complex in case of 50% displacement, $[P]_{50}$ is
 510 concentration of free probe at 50% displacement, $[E]_0$ is concentration of free CaM at 0% displacement,
 511 $K_{D,probe}$ is the dissociation constant of the complex of probe and CaM. The K_D of the probe, F-PMCA
 512 to CaM is 6 nM (Manoharan et al., 2019).

513 The potency of the irreversible covalent inhibitors were assessed as described in (Singh et al., 2011).
 514 The potency and selectivity of a covalent inhibitor are governed by two parameters namely, the K_i , the
 515 affinity constant of the initial non-covalent complex and k_2 , the rate of subsequent covalent bond-
 516 forming reaction as given in the chemical equation,

518 E and I denote a protein target and its covalent inhibitor, respectively. $E \cdot I$ is the initial non-covalent
 519 complex and $E - I$ is the final covalent complex. To obtain the K_i and k_2 rates, the fluorescence
 520 polarization signal after inhibitor treatment was plotted against the incubation time and fit using a one

A covalent CaM-inhibitor tool compound

521 phase decay function to obtain the observed rate constant, k_{obs} . This was repeated for several inhibitor
 522 concentrations. Then, k_{obs} was plotted against the concentration of inhibitor and the data were fit to a
 523 hyperbolic equation, $k_{obs} = \frac{k_2 \times [I]}{K_i + [I]}$ to obtain K_i and k_2 . The ratio of k_2/K_i represents the second order
 524 rate constant of the reaction of covalent inhibitor with the target.

525 5.10 Composite drug activity score

526 The composite drug activity score was obtained by computing the activity of the compounds across
 527 various assays performed. The desired properties taken into consideration are, a high activity in
 528 spheroid assay, higher selectivity for MDA-MB-231 over Hs 578T in spheroid assay, lower toxicity in
 529 2D assay against Hs 578T as compared to MDA-MB-231 cells and higher affinity to CaM. The final
 530 score is obtained using the equation below,

$$531 \quad \text{composite drug activity score} = \frac{DSS_{(MDA-MB-231)}}{DSS_{(Hs\ 578T)}} \times \frac{2D_{toxicity(Hs\ 578T)}}{2D_{toxicity(MDA-MB-231)}} \times \frac{1}{K_d}$$

532 5.11 BRET assays

533 BRET assays were essentially performed as described by others (Lavoie et al., 2013; Bery et al., 2018).
 534 About 100,000 to 150,000 HEK293-EBNA (Meissner et al., 2001) cells were seeded per well of a 12-
 535 well plate in 1 mL of DMEM containing 10% FBS and 2 mM L-glutamine and were grown for 24 h.
 536 Next day, Rluc8-tagged donor and GFP2-tagged acceptor constructs were transfected into cells using
 537 jetPRIME transfection reagent (cat. no. 114-75, Polyplus). Each well was transfected with about 1 μ g
 538 of plasmid DNA using 3 μ L of jetPRIME reagent. For BRET donor saturation titration experiments,
 539 the concentration of donor plasmid (25 ng) was kept constant, and the concentration of acceptor
 540 plasmid was increased from 0 to 500 ng for RasG12V BRET pairs and 0 to 1000 ng for K-Ras/ CaM
 541 BRET pairs. The empty pcDNA3.1(-) plasmid was used to top-up the total DNA load per transfection.
 542 After 24 h of transfection, cells were treated with compounds or vehicle control (DMSO 0.2% v/v in
 543 growth medium) at the specified concentration for 24 h or the stipulated time period in case of the time-
 544 course experiments. The cells from one well of a 12-well plate were collected, washed, and re-plated
 545 in PBS (cat. no. 14190-094, Gibco, ThermoFisher Scientific) on flat bottom, white 96-well plates (cat.
 546 no. 236108, Nunc, ThermoFisher Scientific) as four technical replicates containing 90 μ L of cell
 547 suspension per well. Then fluorescence intensity followed by BRET readings were carried out on a
 548 Clariostar (BMG Labtech) plate reader at 25 °C. The fluorescence intensity (RFU) of GFP2 was
 549 measured with excitation at 405 ± 10 nm and emission 515 ± 10 nm; it is proportional to the acceptor
 550 concentration [acceptor]. BRET readings were taken well by well by adding 10 μ L of 100 μ M
 551 coelenterazine 400a (cat. no. C-320, GoldBio), the Rluc8 substrate to each well (final concentration of
 552 10 μ M) using the injector present in the plate reader. Luminescence emission intensities were
 553 simultaneously recorded at 410 ± 40 nm (RLU, proportional to [donor]) and 515 ± 15 nm (BRET
 554 signal).

555 The raw BRET ratio was calculated as the BRET signal measured at 515 nm divided by emission signal
 556 measured at 410 nm (RLU). The BRET ratio was obtained by subtracting the raw BRET ratio by a
 557 background BRET signal measured for cells expressing only the donor (Bacart et al., 2008) as indicated
 558 in the formula below,

$$559 \quad \text{BRET ratio} = \frac{\lambda_{em\ 515\ nm}_{(donor+acceptor)}}{\lambda_{em\ 410\ nm}_{(donor+acceptor)}} - \frac{\lambda_{em\ 515\ nm}_{(donor\ only)}}{\lambda_{em\ 410\ nm}_{(donor\ only)}}$$

560 With *donor+acceptor* denoting cells transfected with the BRET pair and *donor only* being cells
 561 expressing only the donor.

A covalent CaM-inhibitor tool compound

562 The expression of acceptor relative to donor ([acceptor]/[donor]) was determined as,
563 $relative\ expression = \frac{RFU}{RLU}$
564 For BRET donor saturation titration experiments, the BRET ratio was plotted against the
565 [acceptor]/[donor] ratio. Technical repeat data points were averaged and data points from all biological
566 repeats were collected into one graph for subsequent fitting. The BRET ratio vs relative expression
567 data were fitted using a binding saturation equation in the Prism (GraphPad) software to obtain the
568 $BRET_{max}$ and $BRET_{50}$ using the equation, $y = \frac{BRET_{max} \times x}{BRET_{50} + x}$, where x is the relative expression and y
569 is the BRET ratio. The $BRET_{max}$ represents the maximum saturation BRET signal and depends on
570 structural parameters (distance, orientation) of the BRET complex. $BRET_{50}$ corresponds to the ratio of
571 acceptor construct over donor construct required to attain 50% of the maximum BRET signal and is a
572 measure of the effective relative affinity between the interacting BRET pair (Marullo and Bouvier,
573 2007).
574 When applying the DSS analysis to nanoclustering-BRET data, we used mevastatin (10 μ M) to obtain
575 the asymptote parameter (a) for maximal inhibition effect, as it prevents prenylation of Ras proteins,
576 their plasma membrane trafficking and therefore nanoclustering. Otherwise, normalized BRET ratio
577 data were converted to % inhibition and then subsequently uploaded onto the Breeze site
578 (<https://breeze.fimm.fi/>).
579 Using BRET donor saturation data, the A/D plasmid ratio at which the BRET ratio changes most
580 linearly with the relative expression was determined for each BRET sensor and then used for testing
581 compound treatments.

582 5.12 ATARiS gene dependence score

583 To generate the ATARiS sensitivity plots, excel files corresponding to the normalized viability data
584 for the siRNA knockdown of each gene of interest were downloaded from the publicly available
585 database of the project DRIVE (<https://oncology-nibr.shinyapps.io/drive/>) (McDonald et al., 2017). The
586 Project DRIVE study is a large-scale RNAi screen in which 2D viability effects of mRNA knockdown
587 were assessed (McDonald et al., 2017). The ATARiS algorithm was used in this study to aggregate
588 consistent shRNA activity to gene level activity (Shao et al., 2013). From the excel files of each gene
589 of interest, the sensitivity score data were extracted and a double gradient heatmap plot was generated
590 using Prism (GraphPad). A higher gene dependence (of 2D viability) is indicated by a negative score,
591 while scores zero or above represent no or neutral effects.

592 5.13 Confocal imaging

593 The localization of Ras and CaM fusion proteins were visualized by confocal microscopy. For imaging
594 MDCK cells were cultured in DMEM supplemented with 10% FBS and 2 mM L-glutamine at 37 °C
595 with 5% CO₂. Cells were seeded on glass coverslips 1.5H (cat. no. LH22.1, Carl Roth) in six-well
596 plates (cat. no. 657160, Cellstar, Greiner Bio-One) and plasmids were transiently transfected with
597 jetPRIME. Cells were fixed 48 h after the transfection with 4% paraformaldehyde (cat. no. 43368, Alfa
598 Aesar) in PBS for 10 min at ambient temperature. After washing with PBS-Tween 0.05% (cat. no.
599 9127.1, Carl Roth), DNA was stained with a 1 μ g/mL solution of DAPI (cat. no. D1306, ThermoFisher
600 Scientific) diluted in PBS for 10 min. The coverslips were mounted onto glass slides using Vectashield
601 (cat. no. H-1000, Vector Laboratories). Images were captured on a spinning disk confocal microscope
602 (Andor, Oxford Instruments), fitted with a Zyla 5.5 sCMOS camera (Andor, Oxford Instruments),
603 using a plan APO 60 \times /1.40 Ph3 DM oil immersion objective (Nikon) and NIS-Elements Imaging
604 Software (Nikon).

A covalent CaM-inhibitor tool compound

605 To evaluate the effect of compounds on centrosome numbers during mitosis, HeLa cells were seeded
606 in 6-well plates onto sterile coverslips and co-transfected with 0.5 μg of pmCherry-CaM and 1.5 μg
607 pEGFP-Centrin1 plasmids using 4 μL of jetPRIME. 24 h after the transfection, cells were synchronized
608 with 60 ng/mL of nocodazole for 16 h. After the removal of nocodazole, the cells were treated with the
609 protease inhibitor MG132 (10 μM) to block the cells in metaphase and either calmidazolium (20 μM),
610 **1** (50 μM) or DMSO (0.5%) for 2 h. Cells were then fixed with 4% paraformaldehyde in PBS for 10
611 min at ambient temperature. After washing with PBS-Tween 0.05%, DNA was stained with a 1 $\mu\text{g}/\text{mL}$
612 solution of DAPI diluted in PBS for 10 min. Coverslips were mounted on glass slides using Vectashield
613 and images were captured on a spinning disk confocal microscope. Images were analysed with the
614 ImageJ software and the number of transfected mitotic cells with multipolar and normal bipolar
615 phenotypes were counted (between 35 to 70 cells per test condition). The percentage multipolar versus
616 bipolar cells was computed to generate the plot using the Prism software.

617 5.14 Data analysis

618 All data analysis was performed using Prism (GraphPad) version 9, unless otherwise indicated. The
619 number of independent biological repeats, n , for each data set is provided in the relevant figure legend.
620 Unless otherwise stated, statistical significance was evaluated using one-way ANOVA. A p -value of
621 < 0.05 is considered statistically significant and the statistical significance levels are annotated as: * =
622 $p < 0.05$; ** = $p < 0.01$; *** = $p < 0.001$; **** = $p < 0.0001$, or ns = not significant.

629 aminobenzazulenones (B) tested at a concentration range of 0.6 μM – 40 μM on KRAS-mutant MDA-
630 MB-231 and HRAS-mutant Hs 578T 3D spheroid formation in low attachment condition without
631 serum. Data represent mean values \pm SD, $n \geq 3$. Numbers above the bars indicate the KRAS/HRAS
632 mutant cell line DSS₃ ratios (C,D) The relative toxicity of formyl aminobenzazulenones (C) and
633 aminobenzazulenones (D) was assessed in the CellTox Green assay. Cells were grown as 2D adherent
634 monolayers overnight and then treated for 72 h with 1 μM OphA or 10 μM of the indicated
635 benzazulenones. Data represent mean values \pm SD, $n \geq 2$.
636

637 **Figure 2. Benzazulenones have higher IC₅₀ with less change over time as compared to OphA.**
638 Change of effective CaM-binding affinity over time of OphA and formyl aminobenzazulenones (A)
639 and aminobenzazulenones (B) as measured in the fluorescence polarization assay using F-PMCA
640 peptide as the fluorescent probe. Data represent mean values \pm SD, $n = 2$. Binding curves are plotted
641 in **Figure S2 A,B**. Derived rate analysis plots are in **Figure S2 G,H**.
642

643 **Figure 3. Nanoclustering-BRET assays confirm K-Ras selectivity and fast intracellular activity**
644 **of compound 1 in cells.** (A,B) Testing of top six benzazulenones at 20 μM and 24 h exposure in K-
645 RasG12V (A) and H-RasG12V (B) nanoclustering-BRET assays. Controls are FTI-277 (1 μM), OphA
646 (2.5 μM), mevastatin (10 μM), calmidazolium (20 μM) and prostratin (10 μM). The acceptor/donor
647 (A/D) plasmid ratio of GFP2- and Rluc8-tagged RasG12V was 4/1. Data represent mean values \pm SD,
648 $n = 3$. (C) BRET-DSS₃ values for selected six benzazulenones and OphA, derived from dose response
649 analysis of benzazulenones (0.1 μM – 80 μM) and OphA (0.3 μM – 20 μM) on K-RasG12V and H-

A covalent CaM-inhibitor tool compound

650 RasG12V nanoclustering-BRET data (SI Figure 3A-B). Numbers above the bars indicate the K-
651 RasG12V/H-RasG12V BRET-DSS₃ ratios. The A/D plasmid ratio was 4/1. Data represent mean values
652 \pm SD, $n \geq 3$. (D) K-RasG12V and (E) H-RasG12V nanoclustering-BRET donor saturation titration
653 curves showing the effect of OphA (2.5 μ M), **1** (20 μ M) and vehicle control. Data represent mean
654 values \pm SD, $n = 2$. Note, error bars are very small and may not be recognizable. BRET_{max} data
655 represent mean values \pm SD, $n = 2$. (F) Time-dependent change of K-RasG12V nanoclustering-BRET
656 signal after treatment with **1** (50 μ M), OphA (10 μ M), mevastatin (10 μ M), trifluoperazine (20 μ M)
657 and calmidazolium (20 μ M). The A/D plasmid ratio was 4/1. Data represent mean values \pm SD, $n \geq 2$.
658

659 **Figure 4. Cellular K-RasG12V/ CaM interaction BRET confirms on-target activity of compound**
660 **1 in cells.** (A) BRET donor saturation titration curves between Rluc8-K-Ras or Rluc8-K-RasG12V and
661 N-terminally GFP2-tagged CaM. (B) BRET donor saturation titration curves between the Rluc8-tagged
662 K-Ras oncogenic mutants (K-RasG12C, K-RasG13D and K-RasQ61H) with GFP2-CaM. The
663 BRET_{max} data represent mean values \pm SD, $n \geq 2$. (C) BRET donor saturation titration curves between
664 Rluc8-K-RasG12V or Rluc8-H-RasG12V and GFP2-CaM. Plasmids expressing Rluc8 and GFP2
665 proteins alone were used as controls for non-specific interaction. (D) Compounds calmidazolium (20
666 μ M), prostratin (20 μ M) or OphA (5 μ M), as well as formyl aminobenzazulenone **1** (20 μ M) or non-
667 formylated counterpart aminobenzazulenone **8** (20 μ M) were tested using the Rluc8-K-RasG12V/
668 GFP2-CaM BRET reporter. The A/D plasmid ratio was 9/1. Data represent mean values \pm SD, $n \geq 2$.
669 (E) Dose-response analysis of compound **1** and its non-formylated derivative **8** as compared to OphA
670 using Rluc8-K-RasG12V/ GFP2-CaM BRET signal. The A/D plasmid ratio was 9/1. Data represent
671 mean values \pm SD, $n \geq 2$.
672

673 **Figure 5. Assessment of lysine-dependent CaM-binding activity of OphA, formyl**
674 **aminobenzazulenone 1 and aminobenzazulenone 8.** Time-course of lysine-dependent CaM-binding
675 activity of OphA (A), compound **1** (B) and compound **8** (C) as measured in the fluorescence
676 polarization assay using F-CaMKII peptide as the fluorescent probe. OphA displayed negligible
677 binding with mutCaM compared to wtCaM, hence no IC₅₀ values could be derived (SI Figure 5 A,B).
678

679 **Figure 6. Benchmarking of top compound 1 in several cancer cell lines.** (A) The relative 2D
680 viability of various cell lines following single dose treatment with AMG-510 (1 μ M), calmidazolium
681 (2.5 μ M), OphA (1 μ M) and **1** (10 μ M) was assessed using the alamarBlue assay. Cells were grown as
682 2D adherent monolayers overnight and then treated for 72 h with indicated compounds. Data represent
683 mean values \pm SD, $n \geq 3$. (B) DSS₃ measuring the effects of AMG-510 (0.003 – 40 μ M), calmidazolium
684 (0.3 – 40 μ M), OphA (0.3 – 40 μ M) and **1** (0.6 – 80 μ M). Cells were grown as 2D adherent monolayers
685 overnight and then treated for 72 h. Results represent mean values \pm SD, $n = 3$. (C) DSS₃ measuring
686 the effects of AMG-510 (0.6 – 40 μ M), vemurafenib (0.3 – 20 μ M), prostratin (0.6 – 80 μ M), OphA
687 (0.3 – 20 μ M) and **1** (1.3 – 80 μ M). Cells were grown as 3D spheroids for 72 h then treated with
688 compounds for another 72 h before alamarBlue viability measurements. Data represent mean values \pm
689 SD, $n \geq 2$. (D) Heatmap of ATARiS gene sensitivity scores obtained from the project DRIVE database
690 for KRAS dependent cell lines (MIA PaCa-2, NCI H358 and MDA-MB-231) and HRAS dependent
691 cell lines (Hs 578T and T24). Negative values (red) indicate sensitivity of the cell line proliferation to
692 the knockdown of shown genes, while positive (blue) indicates the opposite.
693

694 **Figure 7. Phenotypic effects of CaM inhibitors on centrosome numbers.** (A) Representative images
695 for bipolar normal (DMSO 0.5%, top) and multipolar centrosomes in HeLa cells after acute treatment
696 for 2 h with calmidazolium (20 μ M, middle) **1** (50 μ M, bottom). HeLa cells expressing mCherry-wtCaM
697 (red) cells were synchronized with nocodazole to G2/M phase for 16 h. Then cells were treated with
698 compounds and simultaneously with the protease inhibitor MG132 (10 μ M). Arrows indicate

A covalent CaM-inhibitor tool compound

699 predominant localization of mCherry-wtCaM on the centrosomes during mitosis. DNA was stained
 700 with DAPI (blue). Scale bar, 5 μm . (B) The multipolar phenotype was quantified for each treatment
 701 from images containing 35 to 70 cells per condition. Data represent mean values \pm SD, $n = 3$. Statistical
 702 significance was evaluated with Fisher's exact test.

703 7 Tables

704 **Table 1. IC₅₀ values of benzazulenones tested on 3D tumorsphere assay.** Data represent mean of
 705 3 biological repeats (Figure S1 E-H).

716 **8 Conflict of Interest**

717 The authors declare that the research was conducted in the absence of any commercial or financial
718 relationships that could be construed as a potential conflict of interest.

719 **9 Author contributions**

720 S.O. designed and performed 3D spheroid assay, 2D cell viability and toxicity studies, BRET assays,
721 DSS analysis, performed the RT-qPCR experiments and cloning together with M.C. G.M. developed
722 the BRET assay, designed, and performed FP assays, and performed cloning. A.K. synthesized the
723 compounds and curated the analytical data. C.L. performed microscopy. M.C. together with G.M.
724 implemented the gateway cloning system, performed cloning, protein purification and RT-qPCR. F.M.
725 contributed reagents and funding support. J.Y-K collaboratively designed the compounds with A.K.
726 S.O. and G.M analyzed all the data. D.A. conceived the study, designed experiments, interpreted
727 results, and wrote the manuscript together with S.O., G.M., A.K. and J.Y-K. All authors commented
728 on the manuscript.

729 **10 Funding**

730 This work was supported by the Finnish Funding Agency for Innovation, Tekes, 3iRegeneration,
731 project 40395/13) and Jane and Aatos Erkko Foundation to JYK. DA received funding from the
732 Academy of Finland (Key Project # 304638) and core funding support by the University of
733 Luxembourg.

734 **11 Acknowledgements**

735 We are thankful to Dr. Dominic Esposito and Vanessa Wall (Frederick National Laboratory for Cancer
736 Research Frederick, MD USA) for providing the entry clones and destination vectors for multi-site
737 gateway cloning. Nina Sipari from Viikki Metabolomics Unit (Helsinki Institute of Life Science,
738 University of Helsinki; Biocenter Finland) is thanked for her expertise with the LC-MS analyses.

1 Supplementary Figures

Supplementary Material

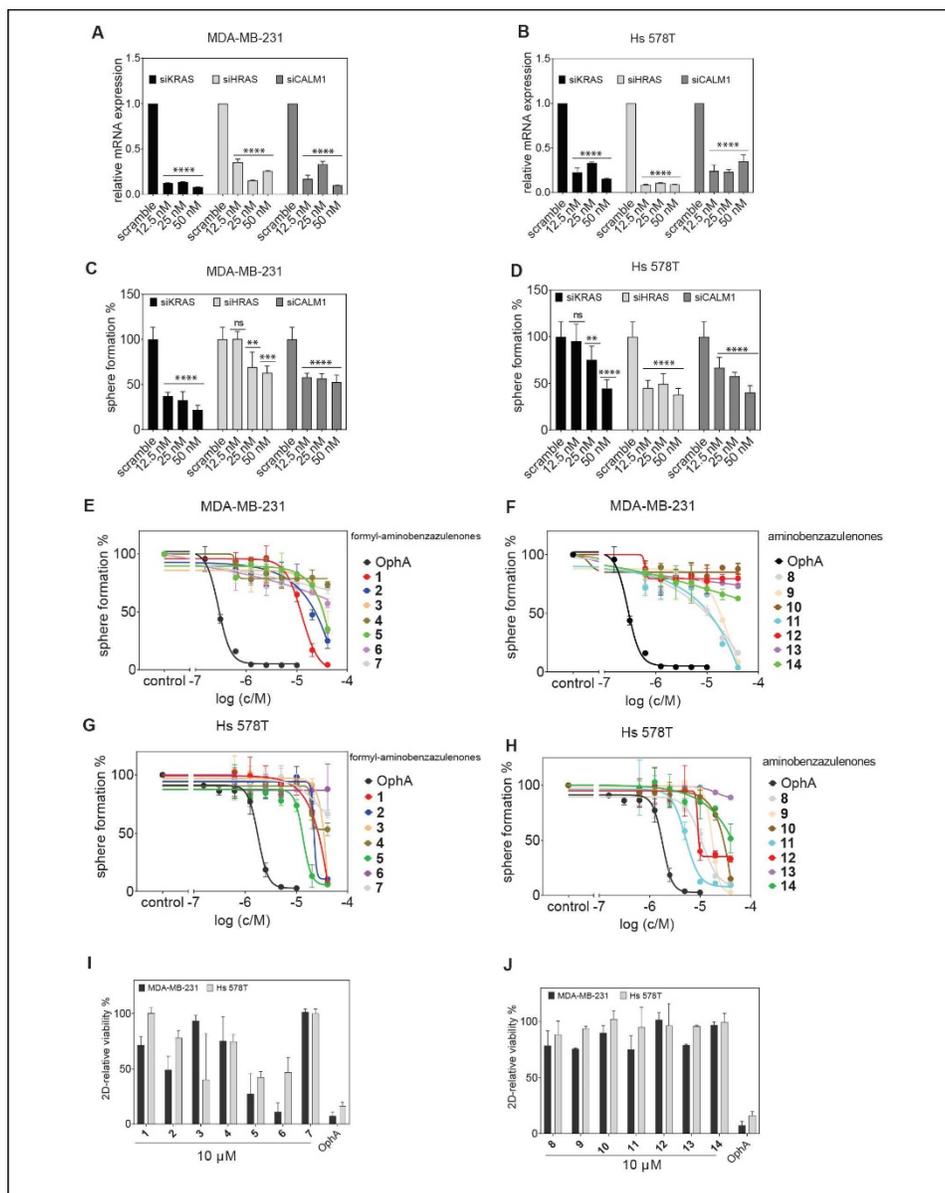

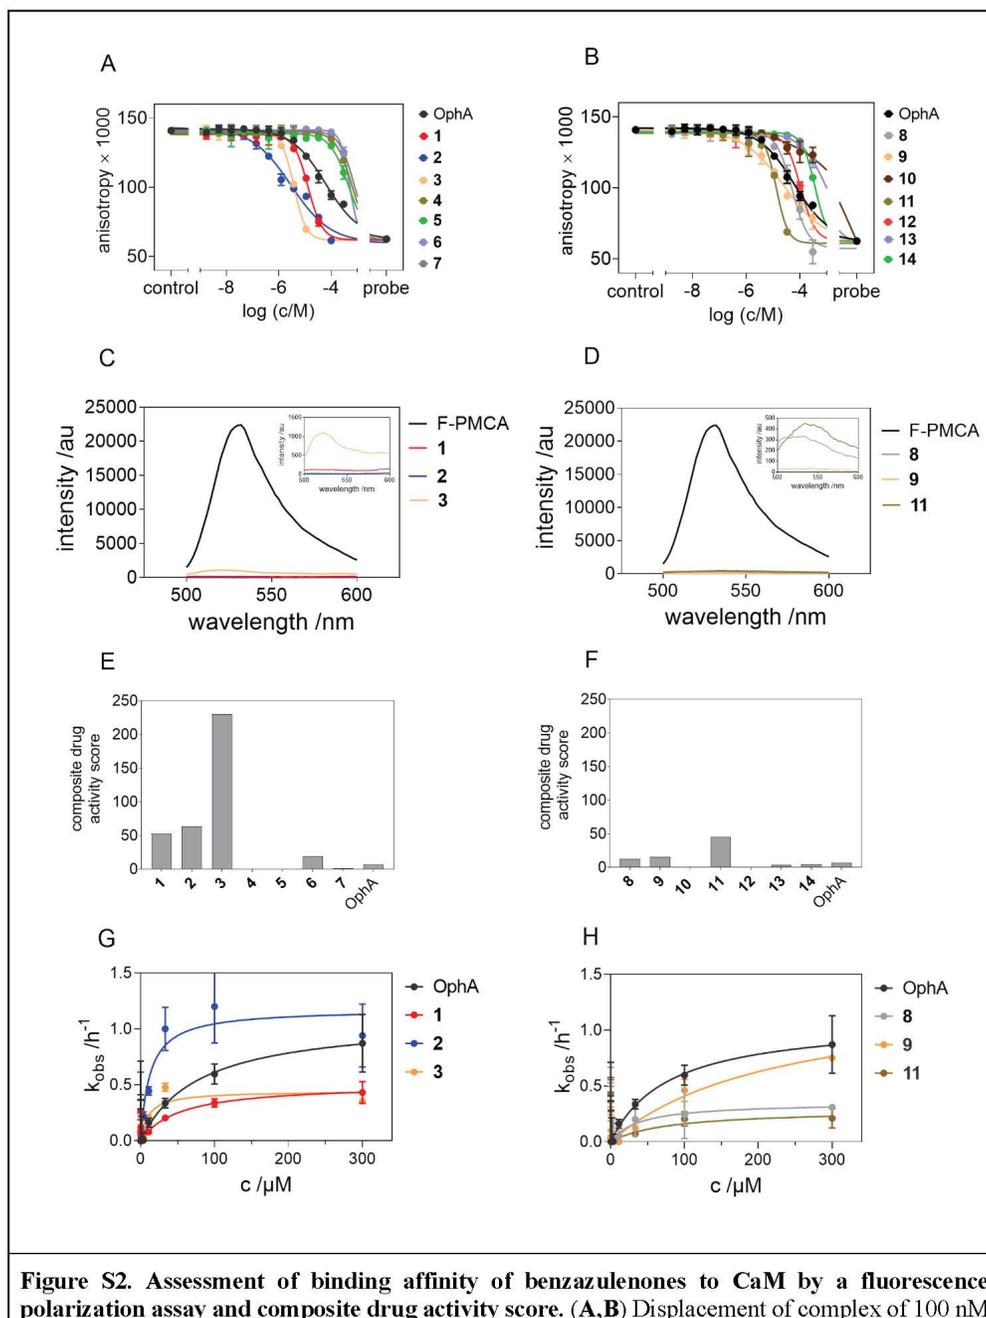

Figure S1. 3D spheroid formation data and knockdown controls. (A,B) RT-qPCR based evaluation of the relative mRNA expression of KRAS, HRAS or CALM1 upon siRNA mediated knockdown in MDA-MB-231 (A) and Hs 578T (B) cells. The siRNA against the KRAS gene (siKRAS), HRAS (siHRAS) and a mix of four siRNAs Targeting the CALM1 gene (siCALM1)

were used for this experiment. Data represent mean values \pm SD, $n = 2$. **(C,D)** Effect of the knockdown of KRAS, HRAS or CALM1 genes on the 3D spheroid formation of MDA-MB-231 (C) and Hs 578T (D) cells in low attachment plates without serum. Data represent mean values \pm SD, $n = 2$. **(E-H)** Dose response curves showing the effect of formyl aminobenzazulenones (0.6 – 40 μ M), aminobenzazulenones (0.6 – 40 μ M) and OphA (0.2 – 10 μ M) on 3D spheroid formation of MDA-MB-231 (E, F) and Hs 578T (G, H) cells, as indicated. Cells were grown as 3D spheroids under low attachment and serum free conditions and then treated 3 days with compounds. The data were fit to log (inhibitor) vs response – variable slope (four parameters) equation using the Prism (GraphPad) software. Note that the actual curve fitting for DSS calculations was done on the breeze-site (<https://breeze.fimm.fi/>). Data represent mean values \pm SD, $n \geq 3$. **(I,J)** The relative viability of the compounds were assessed in alamarBlue assay. Cells were grown as 2D adherent monolayers overnight and then treated for 72 h with 1 μ M OphA or 10 μ M of the indicated benzazulenones. Data represent mean values \pm SD, $n \geq 2$.

Supplementary Material

CaM and 10 nM F-PMCA peptide by formyl aminobenzazulenones (A) and aminobenzazulenones (B) after 24 h incubation. Data represent mean values \pm SD, n = 2. (C, D) Comparison of autofluorescence of compounds with that of F-PMCA. Fluorescence emission spectra were recorded with excitation at 475 ± 10 nm for benzazulenone compounds at 5 mM concentration and 10,000 \times lower concentration of 0.5 μ M for F-PMCA peptide using a Clariostar plate reader. (E,F) Visualization of composite drug activity scores for formyl aminobenzazulenones (E) and aminobenzazulenones (F). Note that **3** was chemically not as stable and therefore deprioritized. (G,H) Hyperbolic fit to observed rate constants in order to derive the covalent step rate constant k_2 and the affinity constant for the non-covalent intermediate K_i .

Supplementary Material

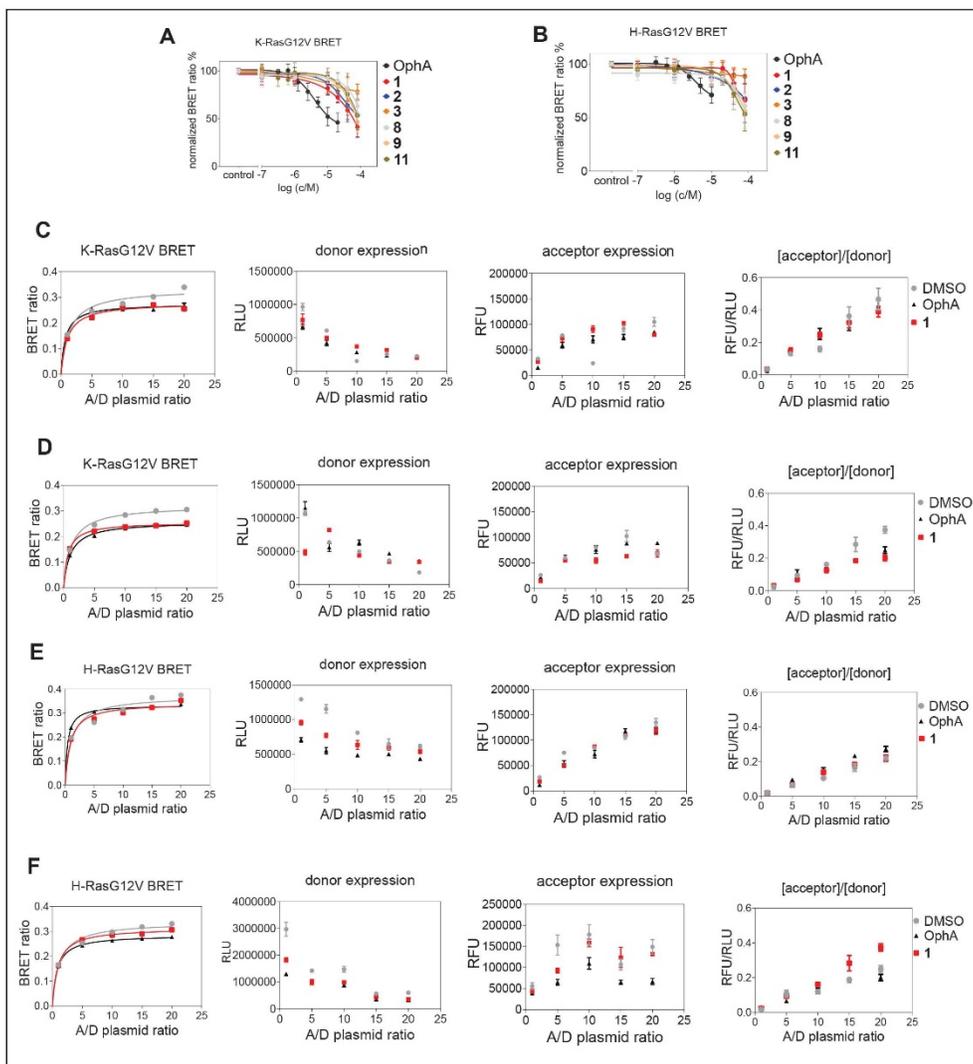

Figure S3. Nanoclustering-BRET assays confirm K-Ras selectivity and faster reactivity of 1 in cells. (A,B) Dose response curves of top six benzazulenones (0.1 – 80 μ M) and OphA (0.3 – 20 μ M) on K-RasG12V (A) and H-RasG12V (B) nanoclustering BRET. The A/D plasmid ratio was 4/1. Data represent mean values \pm SD, $n \geq 3$. The data were fit into log(inhibitor) vs. variable response (four parameters) function was used in the Prism (GraphPad) software to obtain the dose response curve. The actual curve fitting for DSS₃ calculation was done on the breeze-site (<https://breeze.fimm.fi/>). (C-F) BRET ratio vs. acceptor/donor plasmid ratio (A/D plasmid ratio), donor and acceptor expression data of BRET donor saturation titration experiments. Data from BRET pairs of Rluc8- and GFP2-tagged K-RasG12V (E,F) and corresponding H-RasG12V (G,H)

after 24h treatment with DMSO (0.2% v/v in growth medium), OphA (2.5 μ M) or **1** (20 μ M). Each figure group represents individual biological repeats with (left to right) BRET ratio plotted against acceptor/donor plasmid ratio (A/D plasmid ratio), and then donor expression (RLU), acceptor expression (RFU) and relative expression of the two (RFU/RLU) plotted against acceptor/donor plasmid ratio (A/D plasmid ratio). Each biological repeat is the mean of four technical replicates (\pm SD). The BRET ratio vs. relative expression data were fit with a hyperbolic function in Prism to obtain the BRET_{max} and BRET₅₀ values.

Supplementary Material

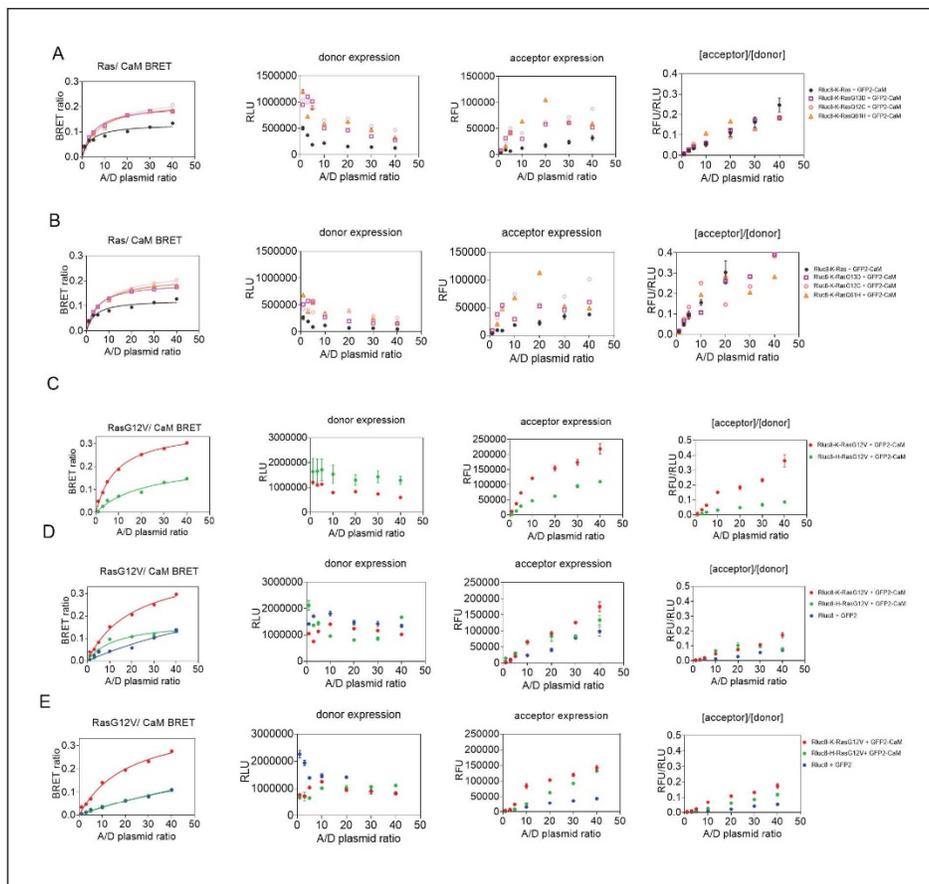

Figure S4. Repeat data of Ras/ CaM BRET experiments. The above figure represents BRET ratio vs. acceptor/donor plasmid ratio (A/D plasmid ratio), donor and acceptor expression data of BRET donor saturation titration experimental repeats for various Ras/ CaM titration curves. **(A,B)** Shows donor saturation titration curves for Rluc8-tagged wild type K-Ras and various G-domain mutants (G12C, G13D, and Q61H) with GFP2-CaM. **(C,D,E)** Shows donor saturation titration curves for Rluc8-K-RasG12V and Rluc8-H-RasG12V with GFP2-CaM. Rluc8 vs GFP2 alone were used to control for unspecific interactions. Each figure group represents individual biological repeats with (left to right) BRET ratio plotted against acceptor/donor plasmid ratio (A/D plasmid ratio), and then donor expression (RLU), acceptor expression (RFU) and relative expression of the two (RFU/RLU) plotted against acceptor/donor plasmid ratio (A/D plasmid ratio). Each biological repeat is the mean of four technical replicates (\pm SD). The BRET ratio vs. relative expression data were fit with a hyperbolic function in Prism to obtain the BRET_{max} and BRET₅₀ values.

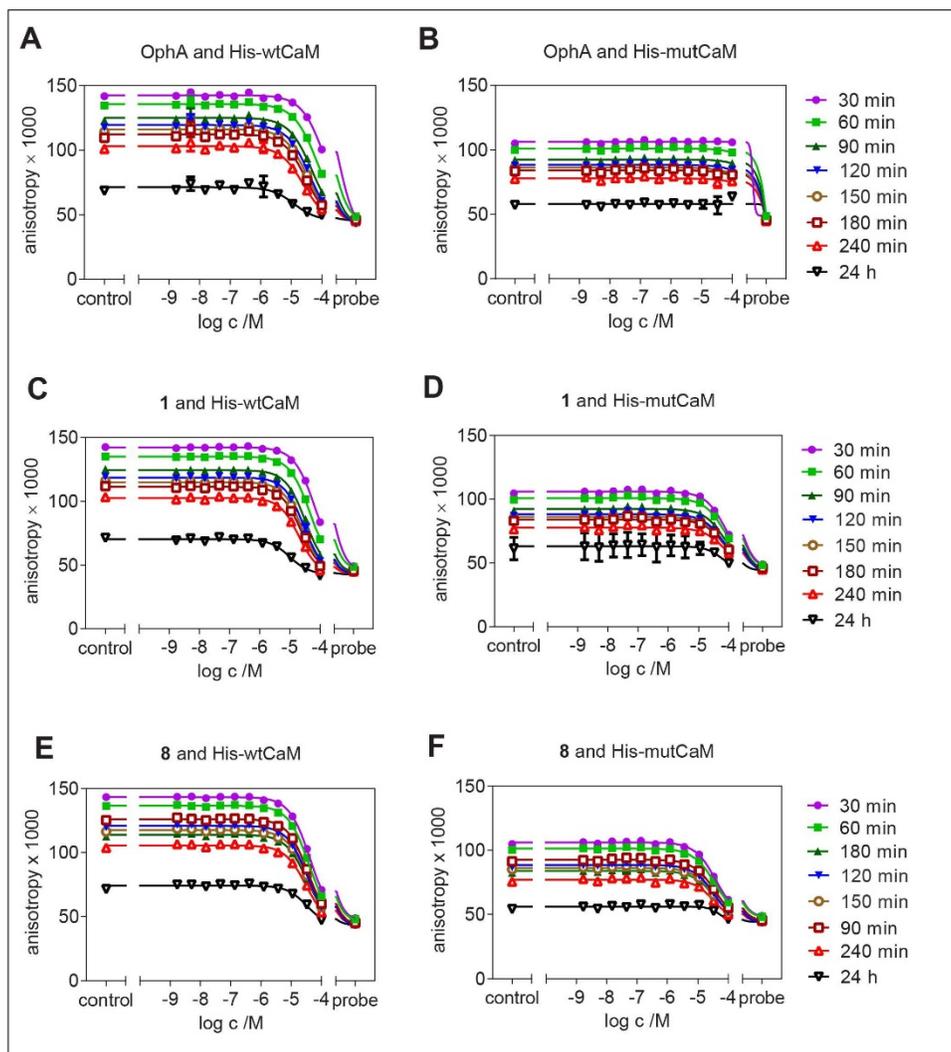

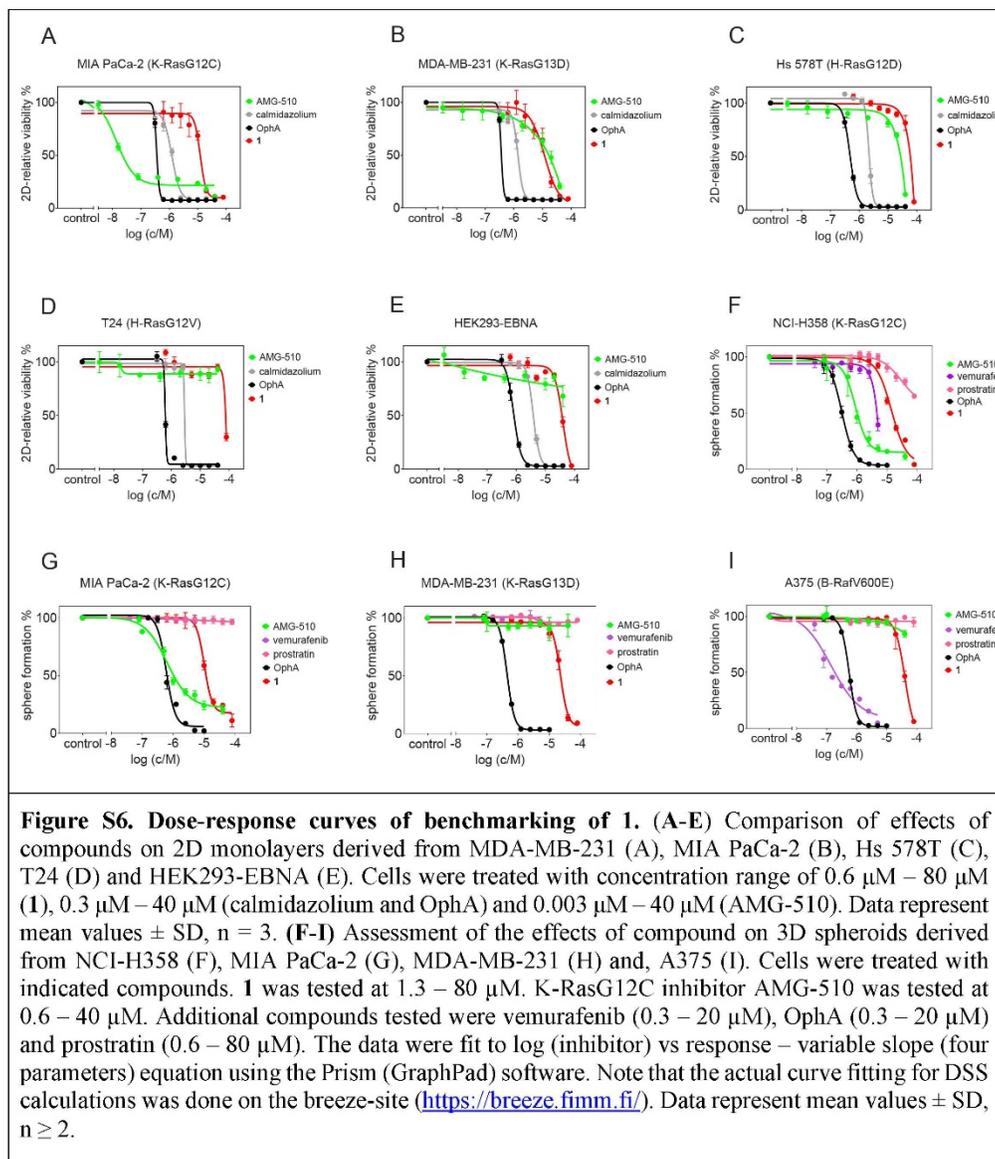

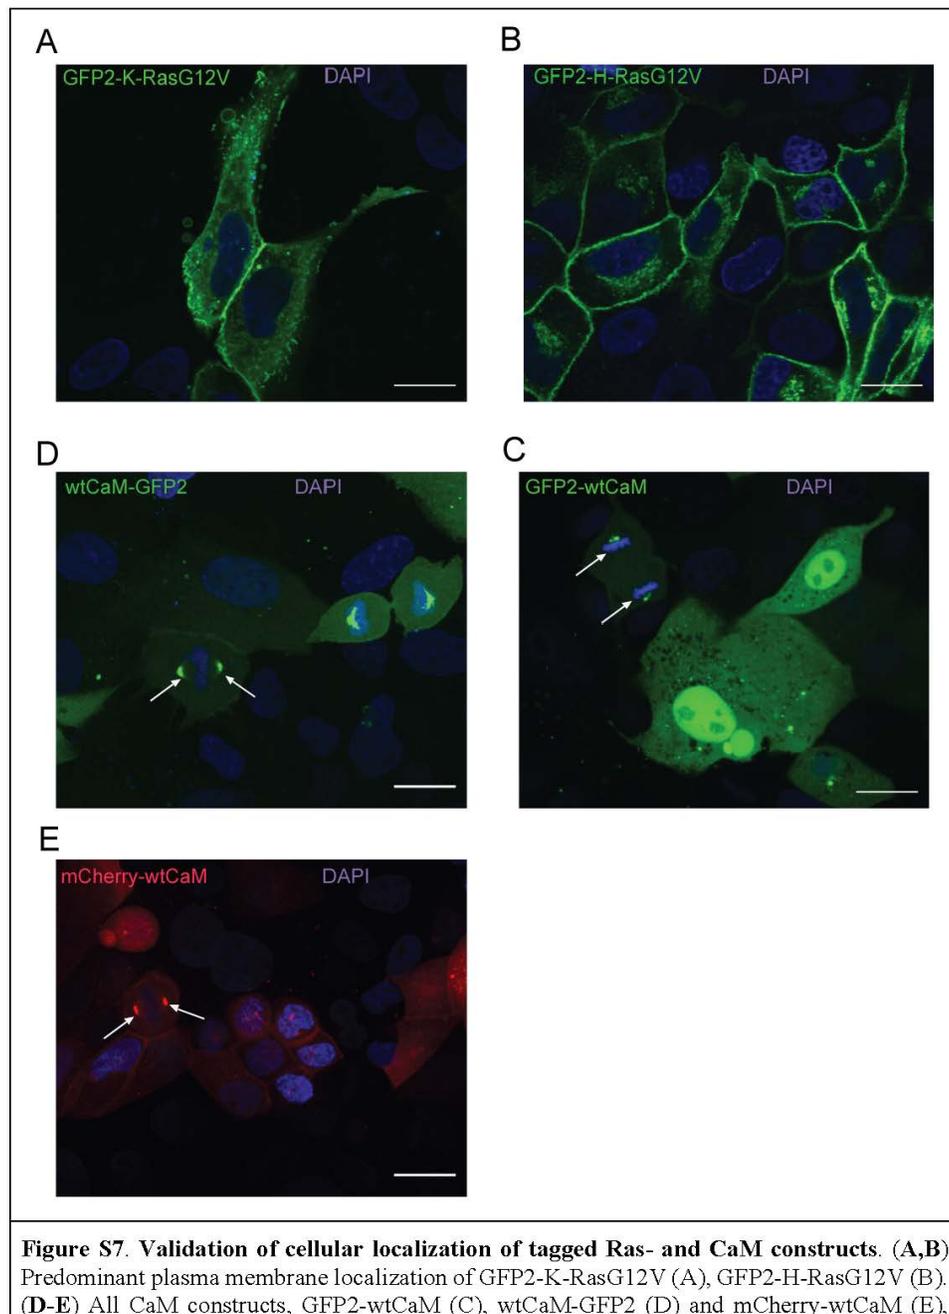

Figure S5. Lysine-dependent CaM-binding activity of OphA, 1 and 8. Displacement of complex of 50 nM His-wtCaM or His-mutCaM and 5 nM F-CaMKII peptide by OphA (A, B), 1 (C, D) and 8 (E, F) at various incubation times. Data represent mean values \pm SD, $n = 3$. The IC_{50} value calculated at each time point was plotted against the time of incubation on **Figure 5**.

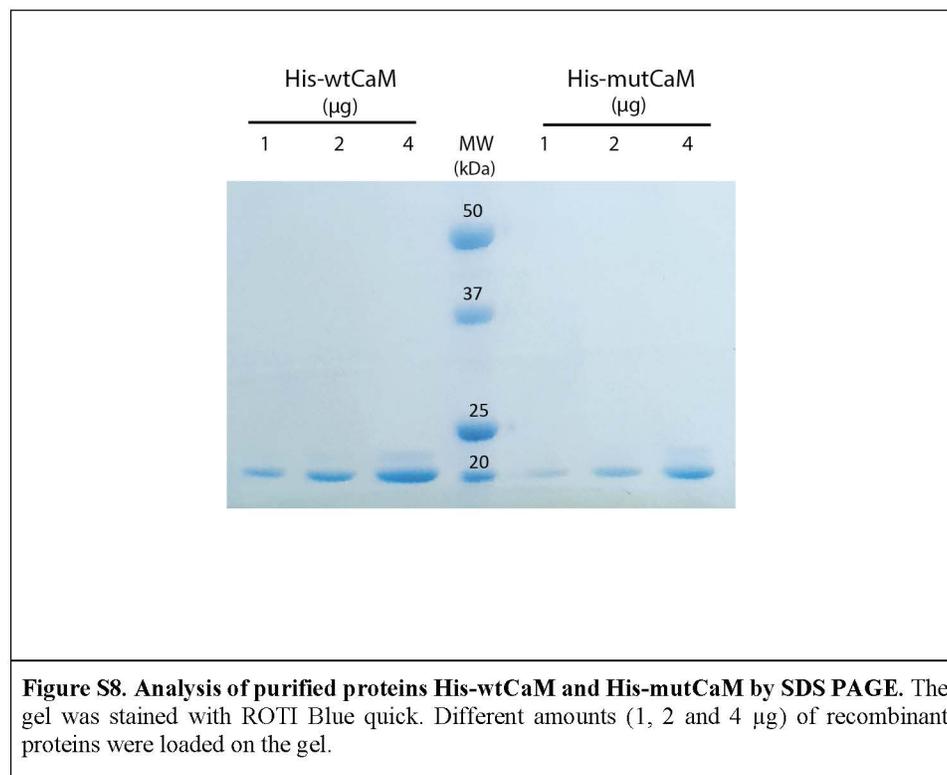

Supplementary Material

Supplementary Material

showed characteristic localization to the centrosomes (pointed arrows) and spindles in mitotic cells. Cell nuclei were stained with DAPI (blue). Scale bars, 20 μm .

Sources:

- All entry clones listed in the table with a code number in parenthesis and destination vectors were obtained from the RAS initiative, FNLCR-NCI, USA
- pDONR257-GFP2-stop (R2-L3) and pDONR235-GFP2-no stop (R5-R1) were commercially cloned at Genewiz Inc., USA. The GFP2 gene was synthesized and cloned into pDONR-235 and pDONR-257 vectors
- The wild type K-Ras4B and H-Ras and the mutant genes were from the RAS mutant collection V2.0 library (kit #1000000089), obtained from Addgene
- pDONR221-wtCaM and pDONR221-mutCaM were commercially obtained from Genecust, France. The wtCaM and mutCaM (containing K75Q, K77Q, and 148Q mutations) were gene synthesized and cloned into pDONR-221 vector using 5' and 3' BsrGI sites

4.3 Potential of phenothiazines to synergistically block calmodulin and reactivate PP2A in cancer cells

Sunday Okutachi, Ganesh babu Manoharan, Daniel Abankwa*

4.3.1 Manuscript 3: Summary

Phenothiazines (PTZs) are a group of clinically approved antipsychotic drugs that in addition to their classical neuroleptic functions, have been implicated as potential anti-cancer agents (Gutierrez et al., 2014, Wu et al., 2016, Jiang et al., 2018). Their ability to pass through the blood-brain barrier as well as their ability to block multiple oncogenic signaling proteins have resulted in great interest in their potential use in managing cancer. Several studies have shown that PTZs inhibit the growth of various cancer types including glioblastomas, melanoma, colorectal cancer and acute lymphoblastic leukemia (Gutierrez et al., 2014, Wu et al., 2016, Jiang et al., 2018). Previous evidence have identified CaM and PP2A within the target spectrum of PTZs (Hait et al., 1987, Gutierrez et al., 2014). Thus, we were interested in assessing the synergistic potential of combining CaM inhibition and PP2A reactivation as a viable anti-cancer therapeutic strategy in Ras driven cancers due to the fact that both CaM and PP2A have been implicated in the regulation of Ras signaling pathways (Villalonga et al., 2001, Wlodarchak and Xing, 2016, Kuo et al., 2008).

Here we showed through a battery of cellular and in vitro assays including 3D spheroids, fluorescence anisotropy assays, BRET assays and western blotting that synergistic inhibition of CaM and PP2A-reactivation has some potential in mitigating Ras driven cancer proliferation and signaling. Importantly, we showed that the PTZ derivative fluphenazine mustard is a potent inhibitor of Ras driven spheroid growth, an inhibitor of Ras membrane organization and confirmed its CaM directed activity through a K-Ras/CaM BRET assay we previously developed. We also show that fluphenazine mustard significantly reduces MAPK signaling output by up to 60% in MIA PaCa-2 pancreatic cancer cell line after just 2 h of treatment. Taken together, our results suggest that fluphenazine mustard is a potent anti-cancer agent with a CaM and potentially PP2A-directed activity in Ras driven cancer cell lines.

4.3.2 Personal contributions of Sunday Okutachi

- Designed, performed and analysed the synergy experiments, 3D spheroid assays as well as the 2D cell viability and toxicity assays
- Designed and generated all BRET assay data
- Performed the DSS analysis on cellular phenotype data and BRET data

- Designed, performed and analysed the western blot experimental data
- Analysed and generated the ATARiS gene dependency profiling of the cell lines

Results

Assessment of the synergistic potential of CaM inhibition and PP2A reactivation in 3D spheroids of Ras-MAPK driven cancer cell lines

It is well established that CaM directly interacts with K-Ras and acts a trafficking chaperone of K-Ras membrane localization and signalling ([Alvarez-Moya et al., 2010](#), [Grant et al., 2020b](#)). PP2A on the other hand modulates signalling of kinases by promoting their dephosphorylation through its phosphatase activity ([Sangodkar et al., 2016](#)). The inhibition of CaM and the reactivation of PP2A have been independent shown to block the growth and proliferation of Ras mutated cancer cell lines ([Najumudeen et al., 2016](#), [Sangodkar et al., 2017](#)).

PTZs have been reported to show both CaM inhibitory and PP2A activating properties ([Hait et al., 1987](#), [Gutierrez et al., 2014](#)). We therefore evaluated the effectiveness of CaM inhibitor calmidazolium (CMZ) and the PP2A agonist DT-061 either as single agents or in combination and compared their activities to that of the PTZ trifluoperazine in a 3D spheroid synergy assay (**Figure 20A,C**). The K-RasG12C specific inhibitor ARS-1620 was used as a test control compound. In this synergy experiment, the full dose response analysis of inhibitors was determined in three Ras/MAPK mutated cancer cell lines MDA-MB-231 (K-RasG13D), NCI-H358 (K-RasG12C) and A 375 (B-RafV600E). The ATARiS gene dependency database was used to profile the cell lines on the basis of their unique genetic dependencies on critical genes of interest (K-Ras, B-Raf, CaM, SET, PPME1) (**Figure 20B**) ([McDonald et al., 2017](#), [Ogris et al., 1999](#), [Cristobal et al., 2012](#)).

When we tested a combination of CMZ and DT-061 in 3D spheroid synergism assays, we observed a 2 to 8-fold increased anti-cancer activity relative to the single agent treatments in three Ras/MAPK mutated cancer cell lines (**Figure 20A**). Interestingly, we observed a similar level of activity for the tricyclic neuroleptic agent trifluoperazine (i.e between 2-7 folds lower than the single agent IC₅₀ values across all 3 cell lines) (**Figure 20A**). The synergy between the two compounds was quantitatively validated with the Bliss synergy scoring algorithm (**Figure 20C; SI Figure 1D**) ([lanevski et al., 2020](#)).

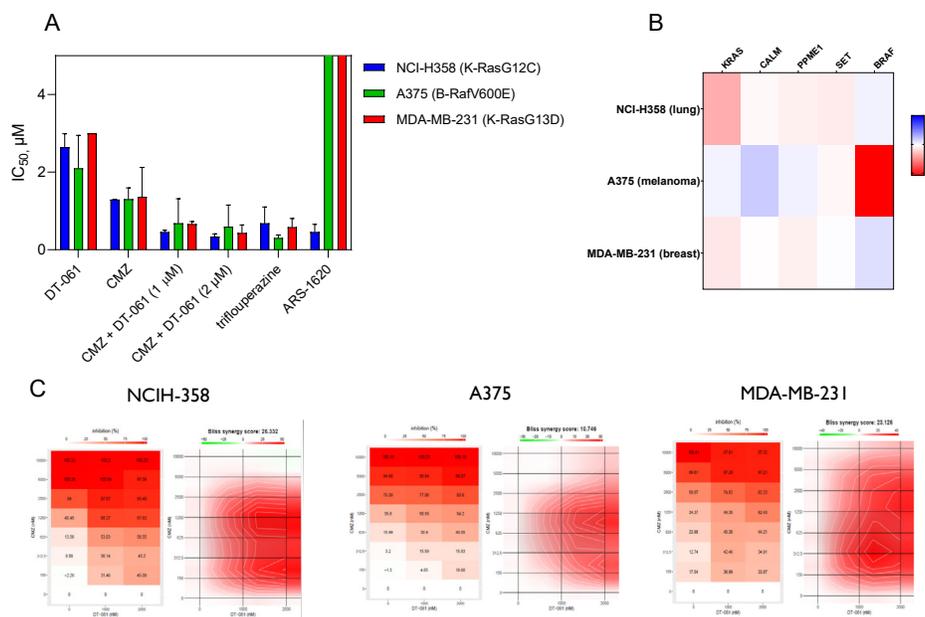

Figure 20. Cellular assessment of CaM inhibition and PP2A activation reveal synergistic potential against Ras pathway dependent cancer cell lines.

(A) IC₅₀ values for various inhibitors in Ras pathway mutant cell lines NCIH-358, MDA-MB-231 and A375 grown in serum free 3D spheroid suspensions. Compounds were tested as either single agents at concentration ranges of 0.2 μM – 10 μM (calmidazolium), 0.6 μM – 40 μM (DT-061), 0.2 μM – 40 μM (trifluoperazine) and 0.6 μM – 40 μM (ARS-1620) or in combination at a full dose response range of 0.2 μM – 10 μM for calmidazolium plus 1 or 2 μM of DT-061 added to all test conditions. Data represent mean values ± SEM, n = 2. **(B)** Heatmaps of ATARiS sensitivity scores of KRAS dependent cell lines (NCI H358 and MDA-MB-231) and BRAF dependent cell lines (A375). Heatmap with negative values (shaded red) indicate sensitivity of the cell line proliferation to the knockdown of shown genes whereas, heatmaps with positive scores (shaded blue) indicates insensitivity of the cell line to the shown gene. **(C)** Representative Bliss synergism heatmaps for combinatorial calmidazolium and DT-061 effects in Ras mutant cancer cell lines. Heatmaps with positive scores (shaded red) indicate synergistic drug interaction whereas, heatmaps with negative scores (green shade on heatmap indicator) indicates antagonistic drug interaction.

Together, these initial findings prompted us to explore in more details the activity of phenothiazines in Ras driven cancers with a primary interest in delineating the potential contributions of covalent modifications to the observed Ras and CaM-directed activity due to our previous work on covalent calmodulin inhibitors (Okutachi et al., under review). Two analogous phenothiazines; the covalent fluphenazine-N-2-chloroethane (hereafter, fluphenazine mustard) and its non-covalent relative fluphenazine hydrochloride (hereafter, fluphenazine) were selected.

In vitro binding studies show improved CaM binding properties of fluphenazine mustard derivative.

We next used a fluorescence anisotropy assay for the determination of the binding affinities of compounds to CaM (**Figure 21B,C**) (Manoharan et al., 2019). The method measures the displacement of fluorescein labelled plasma membrane calcium-ATPase-derived peptide from CaM, compounds with high CaM binding affinities cause a displacement of the peptide resulting in a lower fluorescence anisotropy readout (**Figure 21A**).

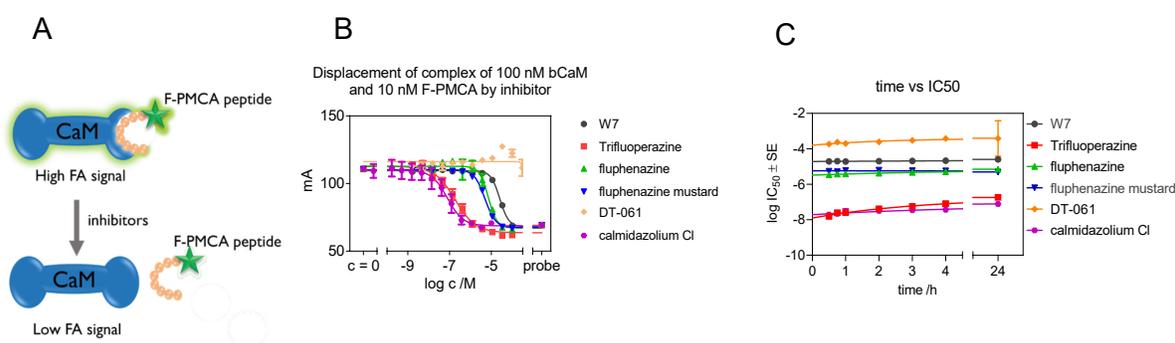

Figure 21. Assessment of binding affinity of compounds to CaM by a fluorescence polarization assay

(A) Schematic model depicting the mechanism of loss of fluorescence anisotropy signal due to the displacement of fluorescein labelled PMCA peptide by CaM binding small molecules **(B)** Displacement of complex of 100 nM bovine CaM and 10 nM F-PMCA peptide by inhibitors. Fluorescence anisotropy measured after 24 h of incubation. Data represent mean values \pm SEM, $n = 2$. **(C)** Dependency of IC_{50} of the inhibitors on time of incubation. In both the figures average of two replicate data with SEM as error is presented. Data represent mean values \pm SE, $n = 2$.

In comparison to calmidazolium ($K_d = 1.09 \pm 0.09$ nM), W-7 ($K_d = 1.51 \pm 0.08$ μ M) appeared to bind at a lesser extent to CaM as demonstrated by the over 1000-fold difference in binding affinity between calmidazolium and W-7. Consistent with its mode of action as a PP2A agonist, we observed that DT-061 binds weakly to CaM ($K_d = 219 \pm 119$ μ M). We observed that trifluoperazine binds with high affinity commensurate to that of calmidazolium ($K_d = 6 \pm 4$ nM) (**Figure 21B**). Interestingly, we observed an over 4-fold improved potency of the covalent fluphenazine mustard to CaM ($K_d = 0.09 \pm 0.02$ μ M) compared with its non-covalent structural relative fluphenazine ($K_d = 0.4 \pm 0.1$ μ M) over a 24 h period of incubation indicating that covalent modification is relevant in improving binding affinity to CaM (**Figure 21B**). Overall, the binding activity of the tested

inhibitors did not significantly change over a 24 hour incubation period when we plotted the IC50 values against time. Hence, none of the tested compounds may be considered to possess a slow CaM reactivity profile (**Figure 21C**).

Cellular BRET assay identify Ras isoform inhibitory properties of covalent fluphenazine mustard.

Using our recently established BRET assay for the identification of compounds capable of selectively inhibiting Ras isoforms specific membrane organization (Okutachi et al., under review), we assessed the effects of DT-061, fluphenazine and fluphenazine mustard on K-Ras vs H-Ras BRET signal output. Inhibitors of Ras membrane organization, Ras chaperone activity inhibitors and post translational modification inhibitors facilitate a measurable loss in the BRET signal which is detected in our assay (**Figure 22A**). In addition to our test compounds, CaM inhibitors calmidazolium, OphA as well as the farnesyl transferase inhibitor FTI-277 were used as controls (**Figure 22B,C,D; SI Figure 2A**).

Consistent with our previous observations, the CaM inhibitors calmidazolium and OphA more selectively decreased the BRET signal of the K-Ras biosensor pairs both at a single concentration and when tested in the full dose response concentration range (**Figure 22B,C,D; SI Figure 2A**). Indeed, we observed a 4-folds selective decrease of K-Ras BRET signal by ophiobolin A and a 2-fold selectivity by calmidazolium in our DSS-BRET analysis (**Figure 22D; SI Figure 2A**). Treatment with the farnesyl transferase inhibitor FTI-277 more selectively decreased H-Ras nanoclustering-BRET (**Figure 22B,C**) due to the alternative prenylation mechanism available to K-Ras4b (Kohnke et al., 2012). However, we fail to observe any significant effect of DT-061 on the BRET signal for both K-Ras and H-Ras biosensor pairs either at a single dose or over several concentration ranges (**Figure 22B,C,D**). Interestingly, whilst fluphenazine did not decrease the BRET signal of either Ras isoform biosensor constructs, the covalently reacting mustard derivative showed a clear effect on both K-RasG12V and H-RasG12V BRET biosensor signalling output albeit without any indication of isoform specific selectivity (**Figure 22B,C,D; SI Figure 2A**).

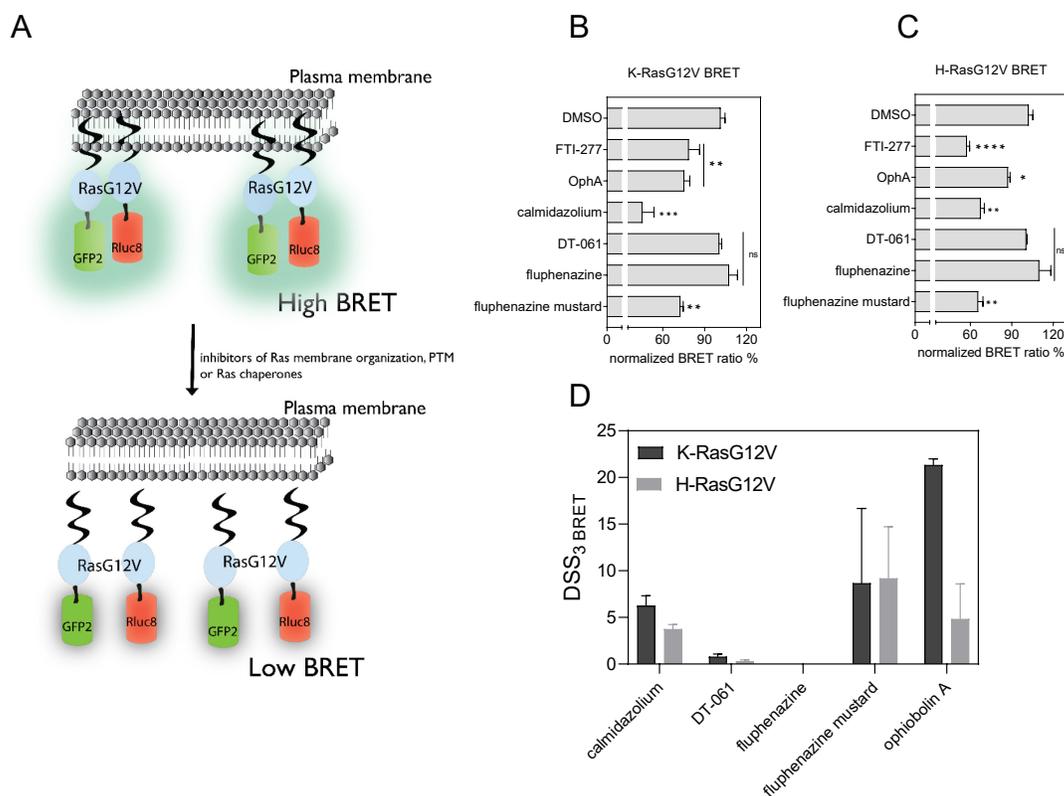

Figure 22. BRET assays identifies fluphenazine mustard as an inhibitor of Ras isoform signaling in cells.

(A) Schematic representation of the mechanism of Ras nanoclustering BRET signal loss due to small molecule perturbation. Compounds capable of disrupting Ras membrane organization, prenyl moiety biosynthesis inhibitors or inhibitors of Ras chaperone activity cause a decrease in Ras BRET signal output. (B,C) Testing of inhibitors at 20 μ M and 24 h exposure in K-RasG12V (A) and H-RasG12V (B) nanoclustering-BRET assays. Controls are FTI-277 (1 μ M), OphA (2.5 μ M), calmidazolium (20 μ M) and DT-061 (20 μ M) (The acceptor/donor (A/D) plasmid ratio of GFP2- and Rluc8-tagged RasG12V was 4/1. Data represent mean values \pm SEM, $n \geq 2$. Statistical differences to vehicle control are annotated as * $p < 0.05$; ** $p < 0.01$; **** $p < 0.0001$; ns, not significant. (D) BRET-DSS₃ values for calmidazolium, DT-061 and fluphenazines derived from dose response analysis (0.1 μ M – 80 μ M) and OphA (0.3 μ M – 20 μ M) on K-RasG12V and H-RasG12V nanoclustering-BRET. The A/D plasmid ratio was 4/1. Data represent mean values \pm SEM, $n \geq 2$.

K-Ras/CaM BRET assays confirms the target engagement activity of fluphenazines in cells.

In order to properly delineate the on-target activity of the fluphenazine derivatives, we assessed their direct effects on the K-Ras/CaM interaction using our Rluc8-K-RasG12V/GFP2-CaM BRET pairs (Okutachi et al., under review). Consistent with our previous observations, CaM inhibitors

ophiobolin A and calmidazolium clearly decreased the BRET signal at single concentrations and over a full dose-response range (**Figure 23B,C; SI Figure 3A**). Similarly, fluphenazine and fluphenazine mustard decreased the BRET signal output thus confirming their CaM on-target activity (**Figure 23B,C; SI Figure 3A**). Interestingly, fluphenazine mustard exhibited a much stronger effect in decreasing the K-Ras/CaM BRET signal as demonstrated by its 3-fold higher DSS-BRET score over fluphenazine (**Figure 23B**). This once again suggests that covalent modification is critical to the improved CaM-directed activity (**Figure 23C**). Further assessment of fluphenazine mustard along with OphA in a donor titration saturation experiment showed that both compounds are effective at decreasing the K-RasG12V/CaM BRET signal over a wide range of increasing acceptor concentrations (**Figure 23D; SI Figure 3B,C,D**).

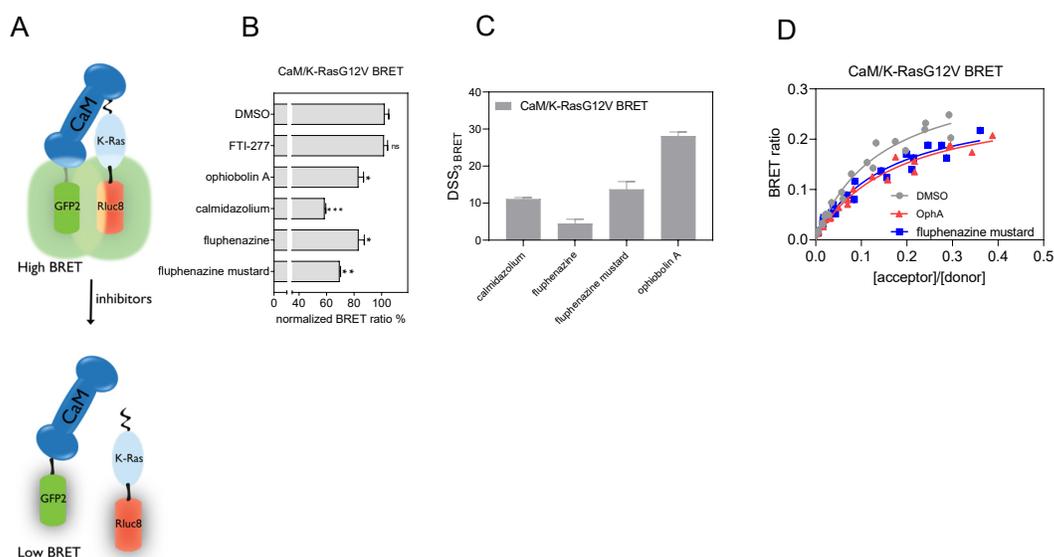

Figure 23. Cellular CaM/K-RasG12V interaction BRET confirms on-target activity of fluphenazines in cells.

(A) Schematic model depicting the hypothetical binding of Rluc8-K-RasG12V to the C-terminus of GFP2-CaM. This interaction produces a high BRET signal which is significantly lower upon small molecule interruption of the complex. (B) Compounds FTI-277 (1 μ M), OphA (5 μ M) or calmidazolium (20 μ M), as well as fluphenazine (20 μ M) and covalent derivative fluphenazine mustard (20 μ M) were tested using the Rluc8-K-RasG12V/ GFP2-CaM BRET reporter. The A/D plasmid ratio was 9/1. Data represent mean values \pm SEM, $n = 2$. Statistical differences to vehicle control are annotated as * $p < 0.05$; ** $p < 0.01$; **** $p < 0.0001$; ns, not significant. (C) DSS₃-BRET values for calmidazolium, DT-061 and fluphenazines derived from dose response analysis and OphA (0.1 μ M – 80 μ M) on Rluc8-K-RasG12V/ GFP2-CaM BRET signal. The A/D plasmid ratio was 9/1. Data represent mean values \pm SEM, $n = 2$. (D) K-RasG12V/CaM BRET donor saturation titration curves showing the effect of OphA (2.5 μ M), fluphenazine mustard (10 μ M) and vehicle control. Data represent mean values \pm SEM, $n = 3$. Note, error bars are small and may not be recognizable.

Synergistic inhibition of CaM and PP2A activation blocks Ras mediated tumor growth and Ras pathway signaling output.

Upon confirming the on-target activity of the phenothiazine derivatives in our cellular BRET assays, we were next interested in characterizing their phenotypic and signaling effects on Ras driven cancer cells. To this end, we performed 2D cell viability experiments using two K-Ras mutated cancer cell lines; MIA PaCa-2 (K-RasG12C) and MDA-MB-231 (K-RasG13D) and the non-malignant human embryonic kidney cell line (HEK-293 EBNA) (**Figure 24A,B; SI Figure 4A,B,C**). We observed that the phenothiazine compounds more selectively inhibited the proliferation of the cancer cell lines by a factor of about 3 to 12-folds higher than HEK-293 EBNA (**Figure 24B; SI Figure 4A,B,C**). Interestingly, we observed that the selectivity was more pronounced in the pancreatic cancer cell line MIA PaCa-2 which we have previously identified to be more dependent on K-Ras based on the data from the ATARiS gene dependency database (**Figure 24B; SI Figure 4A,B,C**) ([McDonald et al., 2017](#)). Indeed, this is consistent with our previous findings where we showed that the inhibitory activity of the novel covalent CaM inhibitor Calmirasone1 correlated with the K-Ras dependency of cancer cell lines (Okutachi et al., under review).

The evaluation of ERK phosphorylation status is well established as an indicator of Ras/MAPK mediated signaling output ([Guo et al., 2020](#)). Therefore, in order to determine the signaling consequences of CaM inhibition and PP2A reactivation, we performed western blot analysis on serum starved and EGF stimulated MIA PaCa-2 cells after a 2 h incubation period with the inhibitors (**Figure 24C,D; SI Figure 4D**). We employed the MEK inhibitor trametinib and the K-RasG12C covalent inhibitor sotorasib (AMG-510) as compound controls whilst DMSO was used as vehicle control. Predictably, both trametinib and sotorasib reduced phospho-ERK signaling output by more than 70% after the 2 h period. DT-061 and calmidazolium both achieved ~30% pERK signal reduction as single agents. However, we only observed a slightly improved (~40%) reduction in pERK output in the combinatorial setup. Interestingly and consistent with its overall activity as a potent CaM inhibitor and potential PP2A agonist, fluphenazine mustard achieved over 60% reduction in pERK signaling output in our western blot experiments thus validating the compound as an effective inhibitor of Ras mediated MAPK signaling output (**Figure 24C,D; SI Figure 4D**).

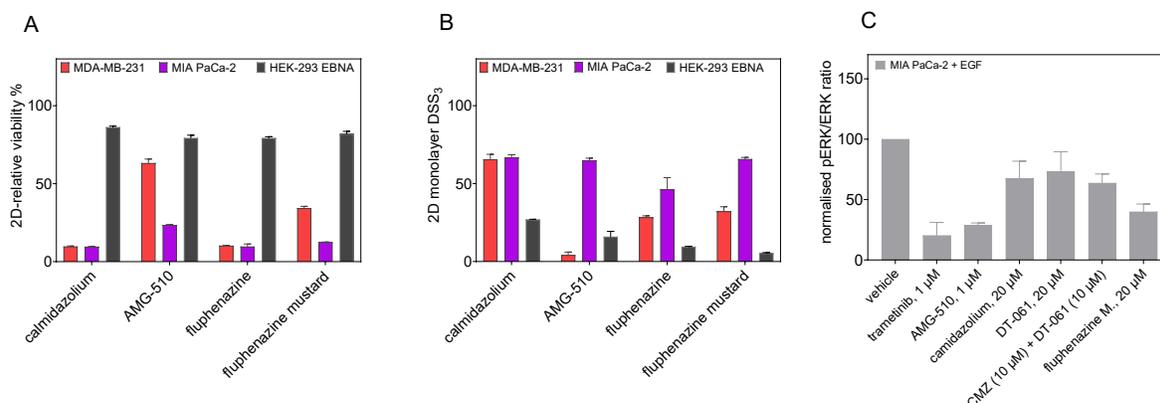

Figure 24. Phenotypic and signaling effects of synergistic targeting of CaM and PP2A.

(A) The relative 2D viability of MDA-MB-231, MIA PaCa-2 and HEK-293 EBNA following single dose treatment with AMG-510 (10 μ M), calmidazolium (2.5 μ M), fluphenazine (10 μ M) and fluphenazine mustard (10 μ M) was assessed using the alamarBlue assay. Cells were grown as 2D adherent monolayers overnight and then treated for 72 h with indicated compounds. Data represent mean values \pm SEM, $n = 3$. **(B)** DSS₃ measuring the effects of AMG-510 (0.003 – 40 μ M), calmidazolium (0.3 – 40 μ M), fluphenazine (0.6 – 80 μ M) and fluphenazine mustard (0.6 – 80 μ M). Cells were grown as 2D adherent monolayers overnight and then treated for 72 h. Results represent mean values \pm SEM, $n = 3$. **(C)** Densitometric quantification of the pERK/ERK ratio analysis. MAPK signaling output was measured in MIA PaCa-2 upon treatment with control compounds trametinib (1 μ M) and AMG-510 (1 μ M), single agent treatment with camidazolium (20 μ M) and DT-061 (20 μ M) or in combination (DT-061 10 μ M + CMZ 10 μ M) as well as fluphenazine mustard (20 μ M). pERK/ERK levels were assessed using a mouse monoclonal antibody against pERK and a rabbit polyclonal antibody against ERK. GAPDH was used as endogenous control for protein expression. Cells were seeded in 6-well plates for 24hrs, serum starved, treated with indicated concentrations of inhibitors for 2 h and then stimulated with EGF for 10 min before lysis. Data represent mean values \pm SD, $n = 3$.

DISCUSSION

5.0 DISCUSSION

5.1 Novel PDE6D inhibitors with a new design principle show K-Ras selective anti-cancer activity

Two major challenges have hampered efforts to develop PDE6D inhibitors namely; the Arl2 mediated ejection mechanism of PDE6D inhibitors and the poor cellular penetration of current PDE6D inhibitors ([Martin-Gago et al., 2017](#)). In this study we developed Deltaflexin 1 and Deltaflexin 2 as proof of concept PDE6D binding molecules able to selectively inhibit K-Ras nanocluster formation in addition to selectively inhibiting the growth of K-Ras driven cancer cell proliferation.

We were able to show that our first generation PDE6D inhibitor Deltaflexin 1 selectively blocked K-Ras membrane organization and selectively inhibited the growth of K-Ras mutated cancer cell lines from different tissue backgrounds including breast, lung and colon. Through structural optimization efforts by replacing the coumarin ring with a terephthalic acid moiety which is similar to deltasonamide (compound 8), and the replacement of the bottom moiety with 2a pharmacologically more stable 2-methyl-substituent on the S-acyl cell penetration group, we improved the overall performance of this new design in the second generation with Deltaflexin 2. Consistently, Deltaflexin 2 showed improved binding and K-Ras selectivity relative to Deltaflexin-1. In general, our Deltaflexins selectively inhibited K-Ras mediated oncogenesis and stemness properties in lung cancer. Similarly, Our new design principle significantly improved the over 1000-fold difference between in vitro and cellular anti-cancer activity of previous PDE6D inhibitors as we could achieve micromolar activity in cells even though our compounds possess micromolar in vitro binding affinity to PDE6D.

Importantly, the siRNA knockdown data for PDE6D and K-Ras in this study suggests that PDE6D downregulation may have K-Ras independent effects on the stemness characteristics of cancer cells. Indeed, inositol polyphosphate-5-phosphatase-E (INPP5E) is a client of PDE6D which is known to localize in the primary cilium via a PDE6D-dependent process ([Humbert et al., 2012](#), [Fansa et al., 2016](#)). Mutations in PDE6D have been implicated in Joubert syndrome, a developmental disorder characterized by distinctive cerebellar structural defects ([Thomas et al., 2014](#)). The potential contribution of INPP5E to the stemness associated anti-cancer activity of PDE6D inhibition is plausible given that ciliogenesis and associated Hedgehog signaling have been recently implicated in the epithelial to mesenchymal transition process and the promotion of

the stemness phenotype in triple negative breast cancer ([Guen et al., 2017](#)). It is also plausible that PDE6D inhibition affects the activity and localization of other client proteins as is the case with drug inhibition strategies against major trafficking hub proteins. Hence, the possibility of alternative-target effects cannot be excluded. Consistently, a recent study with PDE6D inhibitors deltasonamide 1 and 2 conjugated in a PROTAC system showed that the PDE6D degradation increased the sterol regulatory binding protein (SREBP)-mediated gene expression of lipid metabolism enzymes which was accompanied by an increase in the level of cholesterol biosynthesis precursors ([Winzker et al., 2020](#)). This finding highlights the much broader spectrum of functional effects associated with PDE6D inhibition and degradation. Likewise, recent observations that a PROTAC construct of the clinical B-Raf inhibitor sorafenib targets PDE6D emphasizes the relevance of multi-target activity of some approved small molecules in providing clinical benefit. ([Yang Li, 2020](#)). Consequently, off-target and/or multi-target effects might become advantageous particularly in cancers with multiple and diverse sets of driver mutations where the need to drug more than one protein target is desirable.

Although our current Deltaflexins are not suitable to be considered as viable drug candidates, it is important to note that our design approach is compatible with compound-scaffold hybridization of existing PDE6D inhibitors and will consequently be advantageous for the rapid advancement of improved PDE6D derivatives. This strategy may also be adopted for the development of inhibitors for similar lipid binding chaperone proteins such as UNC119, an N-Terminally myristoylated chaperone that facilitates the trafficking of Src Kinases ([Mejuch et al., 2017](#)).

5.2 A novel CaM covalent inhibitor blocks K-Ras/CaM interaction and K-Ras driven cancers

Recent evidence suggests a stemness context specific collaboration of CaM and K-Ras ([Wang et al., 2015b](#)). Disruption of this interaction through prostratin mediated S181 phosphorylation as well as the direct inhibition of CaM by OphA demonstrated anti-cancer activity ([Wang et al., 2015b](#), [Najumudeen et al., 2016](#)). Taken together, these earlier studies indicated that targeting CaM in K-Ras driven cancers may offer a new window of opportunity for CaM drug development ([Najumudeen et al., 2016](#), [Wang et al., 2015b](#), [Saito et al., 2017](#)).

From a small collection of compounds, we have identified **Calmirasone1**, an OphA-like formyl benzazulenenone which binds to CaM with a 4-fold higher affinity relative to OphA. Upon comparison of Calmirasone1 and its non-formylated relative compound 8 in our in vitro CaM binding experiments, we observed that the binding affinity characteristics of the compound that remained unchanged over time was independent of the C-1 formylation since the non-formylated

compound 8 also exhibits this characteristic. We therefore posit that the *ortho* quinone-methide electrophilic reactivity group which possess covalent binding potential is responsible for the unchanged CaM binding characteristic.

Based on the similar selectivity observed for Calmirasone1 and compound 8 in our 2D K-Ras vs H-Ras selectivity experiments, we speculate that the formyl-independent binding of our compounds is also responsible for the unspecific toxicity component of Calmirasone1 activity. However, the over 4-fold increased CaM binding potency observed for Calmirasone1 over compound 8 clearly stems from the C1-formyl group. Importantly, we show that the C1-formyl-dependent activity is lost upon mutations to the Lys 75, 77 and 148 residues of CaM.

Given that the potent CaM inhibitor calmidazolium significantly decreased the BRET-signal of both K-Ras and H-Ras, it is plausible that CaM inhibition affects the membrane anchorage, trafficking and/or nanoclustering of both K-Ras and H-Ras. Indeed, like K-Ras, H-Ras is farnesylated and may potentially employ CaM for trafficking ([Agamasu et al., 2019](#)).

Importantly, cyclic amino group appears to combine several beneficial structural and reactivity properties in Calmirasone1. This is also reflected in cell activity data, where in both 2D and 3D growth experiments, a significant selectivity for KRAS-mutant cells was observed. This suggests a formyl-dependent CaM/K-Ras-directed mechanism of action of these formyl aminobenzazulenones.

Whilst calmidazolium, as well as the covalent inhibitors OphA and Calmirasone1 significantly disrupted K-Ras/ CaM-BRET in cells, we observed that the PKC agonist prostratin did not inhibit the cellular BRET between K-RasG12V and CaM at the tested concentrations. Therefore, prostratin may exert its K-Ras nanocluster inhibition selectivity by a different mechanistic route than inhibition of K-Ras/CaM interaction. Consistent with the BRET data, prostratin also elicited no effect on tumor cell proliferation in the spheroid assays. Although, the structural implication of OphA inhibition of CaM is not yet resolved, the structural evidence from the non-covalent phenothiazine trifluoperazine in complex with CaM shows that binding of trifluoperazine induces a collapse of the original dumbbell shape of CaM into a compact globular structure ([Vandonselaar et al., 1994](#)). It is therefore reasonable to speculate that covalent inhibitors like Calmirasone1 and OphA may elicit a similar effect on CaM conformation and functionality. Indeed, in its collapsed form, the hydrophobic pocket may become inaccessible to both canonical and non-canonical targets including K-Ras ([Vandonselaar et al., 1994](#)).

Clonogenic 3D spheroid growth depends on stemness associated asymmetric and symmetric division processes of cancer cells ([Cicalese et al., 2009](#)). Accordingly, Calmirasone1 demonstrates an efficacy against 3D spheroid growth that correlates with the KRAS-dependence

of the tested cell lines as defined by the ATARiS gene dependency plots. Likewise, it is important to note that the DSS₃-potency of Calmirasone1 reaches about 50% of the clinical K-RasG12C inhibitor sotorasib (AMG-510) (Hong et al., 2020).

Taken together, we have identified Calmirasone1 as a high affinity and easily synthesizable covalent inhibitor of CaM. We showed that Calmirasone1 has a significantly lower unspecific toxicity compared to the natural product OphA. We demonstrated the ability of this compound to selectively and rapidly disrupt K-Ras membrane organization in our BRET assays whilst also showing its ability to directly interrupt the K-Ras/CaM interaction in cells. Importantly, we showed that Calmirasone1 selectively inhibits the growth of K-Ras dependent cancer cells under both 2D monolayer and 3D spheroid conditions.

CaM has been implicated in several biological processes including cell cycle regulation, cell division, apoptosis, invasion and migration etc. (Berchtold and Villalobo, 2014). The inhibition of CaM is known to affect cell division processes including cleavage furrow formation (Yu et al., 2004). Indeed, the quinazolinone compound mdivi-1 which induces multipolar acentrosomal spindles was shown to kill cancer cells (Wang et al., 2015a). Our cell biological experiments with Calmirasone1 ($K_d = 0.87 \pm 0.02 \mu\text{M}$) and the potent non-covalent CaM inhibitor calmidazolium ($K_d = 13.5 \text{ nM}$) indicated that only Calmirasone1 significantly induced a multipolar phenotype despite the ~80-fold higher in vitro binding affinity of calmidazolium to CaM.

Conclusively, although Calmirasone1 does not possess desirable characteristics for progression into a viable clinical agent, its utility as a tool compound for further studies into the mechanism of the K-Ras/CaM associated cancer stemness mechanism will be insightful. Similarly, Calmirasone1 may be applied to acutely and rapidly achieve a chemical knock-down of all CaM in cells in a more efficient manner than with the most potent non-covalent inhibitor calmidazolium. This application may find relevance in many aspects of CaM biology beyond cancer research due to the central role of CaM in modulating cellular processes across species (Berchtold and Villalobo, 2014).

5.3 Synergistic targeting of CaM and PP2A in K-Ras driven cancers

To effectively suppress K-Ras driven cancers, the use of inhibitor combinations and/or the development of inhibitors capable of blocking several signalling proteins relevant to Ras activation is pertinent. Here, we show that fluphenazine mustard, a potent tricyclic PTZ containing an alkylating chloroethylamine chain possesses improved anti-CaM activity through a variety of assays. Unlike fluphenazine dihydrochloride, fluphenazine mustard irreversibly inhibits CaM (Hait et al., 1987). We show an over 4-fold higher affinity for CaM by the mustard derivative compared

to fluphenazine thus suggesting that the chloroethylamine moiety is central for improved anti-CaM directed covalent activity in vitro since this is the only structural difference between the two compounds. We could also show that DT-061 failed to bind effectively to CaM consistent with its mechanism of action as a PP2A A α scaffold subunit binder and stabilizer of the B56a-PP2A holoenzyme.

Consistent with the earlier mentioned importance of the alkylating chloroethylamine group for improved anti-CaM effects, our Ras nanoclustering BRET assays confirm that fluphenazine mustard reduced both K-Ras and H-Ras membrane interaction. Indeed, this significant decrease the BRET signal of both K-Ras H-Ras by a covalent CaM inhibitor highlights our previous observation that membrane anchorage, trafficking and/or nanoclustering of both K-Ras and H-Ras are susceptible to CaM inhibition (Okutachi et al., under review). Interestingly, DT-061 did not show any appreciable effect on the membrane anchorage of both Ras isoforms. This indicates that the compound's mechanistic binding to the PP2A A α scaffold subunit and subsequent stabilization of the B56a-PP2A holoenzyme has no direct impact on Ras membrane dynamics (Leonard et al., 2020). In the same vein, fluphenazine mustard maintained a 3-fold higher DSS-BRET score over fluphenazine in our on-target K-Ras/CaM experiments, thus further validating the relevance of the chloroethylamine alkylating modification for improved CaM activity.

Upon western blot assessment, we show that fluphenazine mustard already achieves an over 60% reduction in pERK signalling output, an important indicator for cellular Ras activity. The effect of fluphenazine mustard was higher than those of single agent CMZ and DT-061 over the 2 h treatment period. Further phenotypic assessment by 2D proliferation assays also confirms the ability of the compound to inhibit the growth of Ras mutated cancer cell lines.

Although we were unable to directly assess the binding of the phenothiazines to PP2A as a result of the difficulty in establishing an in vitro binding assay with the fully functional PP2A protein, the use of indirect approaches to measure PP2A effects may become relevant in this study. The tumor suppressor activity of PP2A is known to be mediated through its ability to dephosphorylate diverse targets implicated in cancer (Gutierrez et al., 2014). Therefore, by assessing the dephosphorylation status of PP2A targets such as AKT, p70S6K, MYC, ERK and BAD upon fluphenazine mustard treatment, an indirect measure of PP2A activity can be achieved. However, notwithstanding the current experimental limitation, the highly similar structure of DT-061 to phenothiazines which differs essentially by the replacement of the basic amine group of the phenothiazines with a polar functional group, allows us to speculate that fluphenazine mustard may also bind to PP2A (Kastrinsky et al., 2015). Consistently, it has been documented that

perphenazine, another structurally similar phenothiazine elicits its anti-tumor activity by PP2A reactivation ([Gutierrez et al., 2014](#)).

While our study is quite limited, it suggests that preservation of the CaM inhibitory activity of PTZ derivatives that can also activate PP2A is desirable. Our data show however, that DT-061 does not bind to CaM and would therefore have lost the synergistic potential. We propose that the preservation of the investigated polypharmacology of PTZ could allow for a higher, yet selective cancer cell killing activity.

CONCLUSIONS AND PERSPECTIVES

6.0 CONCLUSIONS AND PERSPECTIVES

Renewed interest in Ras drug development, potentiated by the development of the covalent G12C inhibitors has led to a significant increase in the body of knowledge on Ras therapeutic targeting. Since entering clinical trials, some studies have already identified resistance mechanisms against these inhibitors (Tanaka et al., 2021, Dunnett-Kane et al., 2021). Indeed, the differences in Ras isoform tumorigenic abilities brought about by the interplay between multiple factors such as Ras gene dosage, differential isoform specific signaling as well as the contribution of tissue or cellular contexts that dictate genetic, epigenetic and proteomic landscapes, makes the effective targeting of Ras driven cancers a daunting challenge (Prior et al., 2020). Therefore, to effectively treat K-Ras mutated and/or K-Ras driven cancers, the need to pursue multiple direct and indirect therapeutic strategies including the targeting of K-Ras trafficking chaperones as well as the synergistic targeting of different nodes in K-Ras mediated signaling pathways will be crucial.

In my PhD thesis, the overarching aim was to identify novel small molecules that can interfere with K-Ras membrane localization through the inhibition of K-Ras trafficking chaperones by both covalent and non-covalent binding. To this end, we designed and developed relevant assays for the in vitro and in cellulo characterization of small molecules against the trafficking chaperone proteins CaM and PDE6D. Collectively, the findings of this thesis show that the inhibition of the K-Ras trafficking chaperones clearly interferes with proper K-Ras membrane localization, and signaling. Consistently, we established that blocking the K-Ras chaperone activity of PDE6D and CaM with Deltaflexins and Calmirasone1 blocked 2D and 3D proliferation of K-Ras mutated cancer cell lines. Consequently, the compounds Deltaflexin 1, Deltaflexin 2 and Calmirasone1 identified in this thesis may become useful tool in the further interrogation of the activities of PDE6D and CaM particularly in the context of the K-Ras associated cancer stemness phenotype. Among the Ras isoforms, K-Ras has the greatest potential to induce stemness traits (Quinlan et al., 2008, Chippalkatti and Abankwa, 2021). To properly unravel the mechanistic details of this K-Ras associated cancer stemness phenomena, it may be insightful to look beyond the canonical K-Ras plasma membrane localization/ functions and explore other activities and localizations implicated in cell fate decision making. This K-Ras stemness traits potentially enabled by the activity of trafficking chaperones CaM and PDE6D due to both proteins being dynamically localized and relevant for the organization and functions of cell fate linked cellular machineries like the centrosome and primary cilium highlights the importance of having useful tool compounds to study this process.

Beyond K-Ras specific anti-cancer effects, drugging PDE6D has the potential to provide therapeutic benefit for disease conditions where other PDE6D clients are relevant. For instance, PDE6D have been implicated in the development of Joubert syndrome and ciliopathies (Thomas et al., 2014, Fansa et al., 2016). Likewise, a recent study identified targeting the Rap1-PDE6D interaction in Alzheimer's disease models as a promising therapeutic strategy for protection against the neurodegenerative disease further highlighting the importance of PDE6D inhibition beyond the cancer context (Dumbacher et al., 2018).

Covalent inhibitors have experienced a renaissance in the past few years (Singh et al., 2011). Covalent inhibitors possess significant advantages including the fact that covalently reacting chemical warheads can target specific amino acid residues of a particular target protein, thus leading to the development of highly selective inhibitors (Singh et al., 2011, Aljoundi et al., 2020). Whilst the majority of rational covalent drug development efforts have focused on cysteine modifying small molecules, there is significant opportunity in the less explored area of lysine-modifying covalent inhibitor development (Singh et al., 2011). Our work with Calmirasone1 and OphA here exemplifies the potential applicability of a lysine modifying covalent inhibitor in oncology studies. Indeed, our novel covalent CaM inhibitor Calmirasone1 will add to the arsenal of covalent tool compounds to study CaM-associated cell biological processes specifically in unravelling the K-Ras/CaM associated stemness activity.

Developing effective anti-cancer agents not only requires new compounds but also the rational repurposing of already approved drugs for different diseases if they show significant anti-cancer benefits (Armando et al., 2020). Phenothiazines have been applied for the management of neurological conditions such as Schizophrenia for several decades and their safety for clinical applications is well documented. PTZs in addition to their neuroleptic effects have been reported to block cancers through the inhibition of CaM and PP2A activity (Hait et al., 1987, Gutierrez et al., 2014). Our findings in this thesis adds to the existing body of knowledge that these compounds possess relevant anti-cancer properties through multi-target engagement characteristics.

The following perspectives emerge from the results of this thesis:

- Building on our validation of the new design principle of PDE6D inhibitors, compounds with improved binding characteristics and resilience to Arl2-GTP unloading should be developed.

- To unravel the role of K-Ras in the emergence of cancer stem cells, the application of Calmirasone1 as a tool compound will be useful to aid the dissection of the role of K-Ras and CaM in cell fate determination.

- We have not fully studied the off-target activity of our CaM inhibitors, it is therefore plausible that CaM related proteins such as centrin-1, an EF-hand containing calcium binding protein with broad structural and functional similarity to CaM ([Dantas et al., 2012](#)), can also react with our compounds. Hence, the use of mass spectrometry to identify the full target-spectrum of our novel CaM inhibitor Calmirasone1 may be instructive in identifying any potential off-targets.

- In addition to being a cheaper option, another advantage of repurposing phenothiazines for oncology indications could be their already optimized chemistry for passage through the blood-brain barrier. Glioblastoma multiform (GBM) is a very aggressive form of brain cancer lacking sufficient beneficial therapeutic interventions ([Shergalis et al., 2018](#)). GBM is known to be reliant on Ras signaling in vivo ([Holmen and Williams, 2005](#)). Since the work of this thesis identifies a relationship between phenothiazine anti-cancer effects and Ras-MAPK dependence of cancers, it will be interesting to assess the activity of these compounds in GBM disease models.

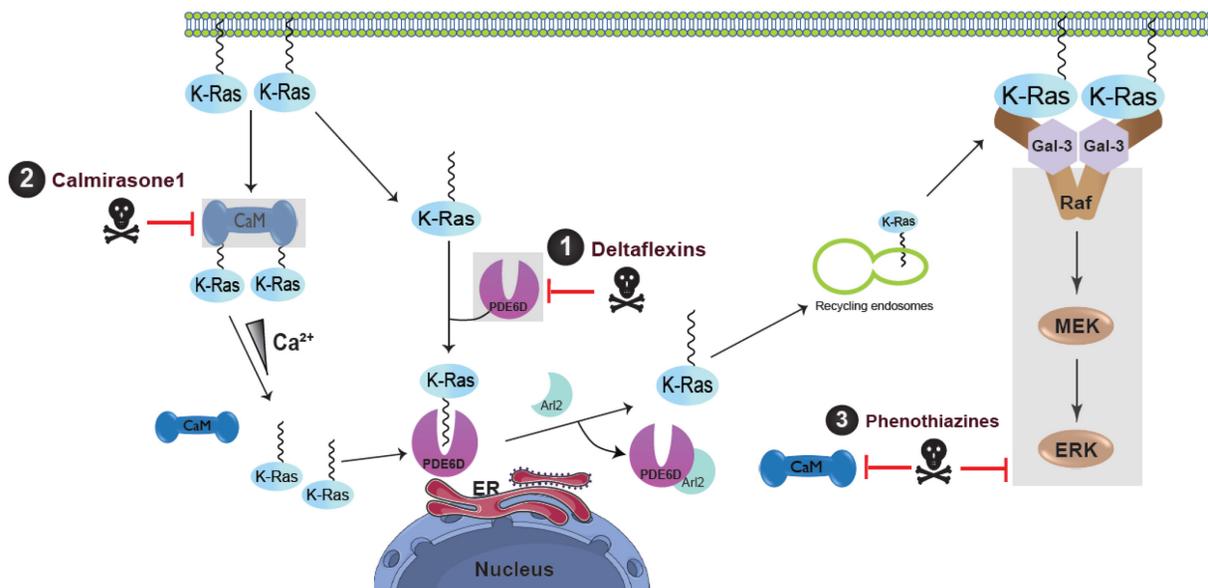

Figure 25. Schematic summary of thesis.

In this thesis, we developed and characterized novel covalent and non-covalent small molecules against K-Ras trafficking chaperones PDE6D (Deltaflexins) (1) and CaM (Calmirasone1) (2). Our results show that inhibiting these proteins more selectively interfered with K-Ras membrane localization and signaling. Similarly, we assessed the activity of phenothiazines which are reported CaM inhibitors and PP2A agonists (3) and show that these compounds decrease Ras-MAPK signaling output via a CaM and potentially PP2A dependent process.

Appendices

SI Table 1. List of CaM inhibitors and their mechanisms of action in cancer

Table 7. List of CaM inhibitors and their mechanisms of action

#	Compound	Effects/Mechanism	Reference(s)
1	trifluoperazine	CaM antagonist, promotes apoptosis and necrosis in pancreatic adenocarcinoma	(Weiss et al., 1980, Huang et al., 2019)
2	E6 berbamine	CaM inhibitor, exerts anti-cancer effects on colon cancer cell line HT-29 by inducing autophagy and apoptosis	(Hu et al., 1992, Mou et al., 2019)
3	polistes mastoparan	Anti-cancer peptide that blocks mammary carcinoma in mouse through CaM inhibition	(Barnette et al., 1983, Hilchie et al., 2016)
4	CGS-9343B	CaM inhibitor that blocks gastric acid secretion in vitro and in vivo	(Norman et al., 1987, Black et al., 1989)
5	artemisinin (tehranolide)	CaM inhibitor which selectively blocks proliferation of K562 leukemia cell line	(Noori and Hassan, 2014)
6	CBP501	Blocks cancer proliferation, migration, EMT in NSCLC and suppresses macrophage induced CSC phenotypes through CaM inhibition	(Saito et al., 2017, Mine et al., 2017)
7	chlorpromazine	Blocks T-cell invasion across fibroblast monolayers through CaM inhibition	(Grabski et al., 2001)
8	flunarizine	Inhibits growth and survival of B16 mouse melanoma cell line through CaM/Ca ²⁺ antagonism	(Sezzi et al., 1984)
9	J8	Antagonist of CaM, inhibits human melanoma cell invasion through fibronectin	(Dewhurst et al., 1997)
10	calmidazolium	Directly binds to CaM, inhibits cell adhesion and proliferation of colon cancer cells. Also reported to inhibit cancer stemness characteristics	(Lee et al., 2016, Najumudeen et al., 2016)

Appendices

11	ophiobolin A	Covalently modifies Lysine residues on CaM, shown to block spheroid formation of Ras mutant breast cancer cell lines	(Najumudeen et al., 2016)
12	fluphenazine	CaM antagonist with anti-cancer effects on metastatic triple negative breast cancer	(Xu et al., 2019)
13	fluphenazine mustard	CaM covalent antagonist, sensitize lung cancer cell line H1299 to trail induced apoptosis	(Hwang et al., 2009)
14	W-7	Non covalent CaM antagonist shown to inhibit tumor cell growth, migration, invasiveness and metastasis in vivo	(Mohri et al., 1998 , Parker and Sherbet, 1992 , Ito et al., 1991)
15	miconazole	CaM inhibitor with activity against CaM mediated PDE activity	(Hegemann et al., 1993 , Breitholtz et al., 2020)
16	econazole	CaM inhibitor with activity against CaM mediated PDE activity	(Hegemann et al., 1993)

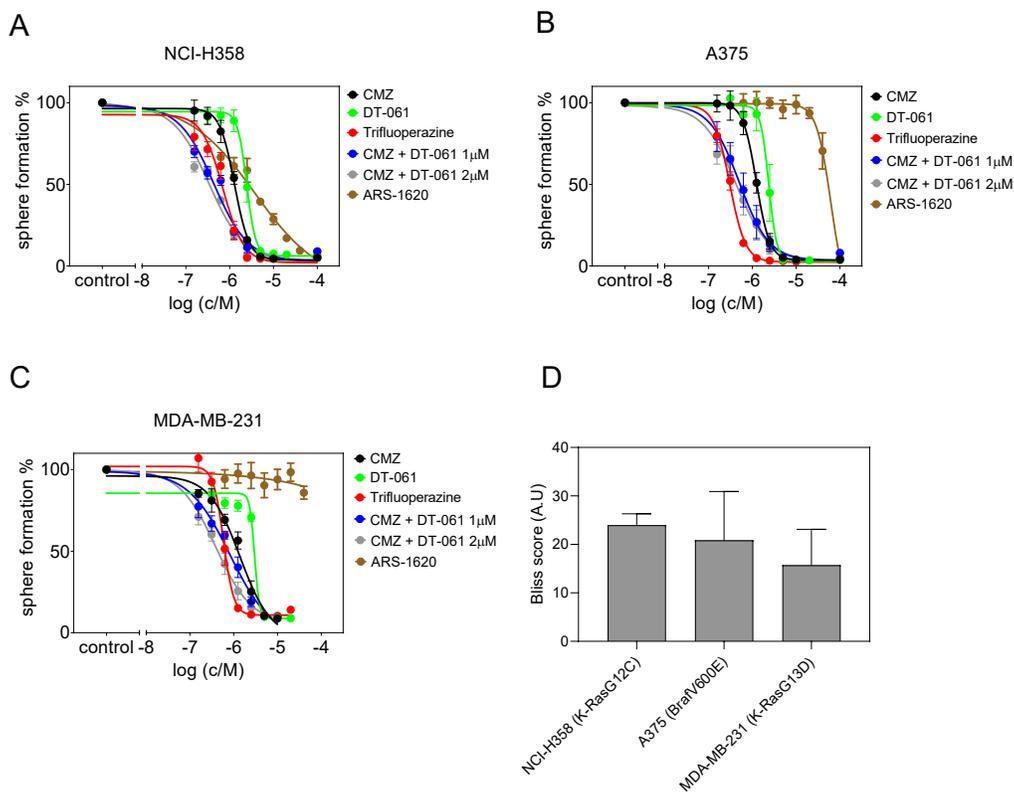

Supplementary information for Manuscript 3: Phenothiazines synergistically block calmodulin and reactivate PP2A in Ras-MAPK driven cancers

SI Table 2. IC50 values of compounds assessed in 3D synergism spheroid assays N = 2

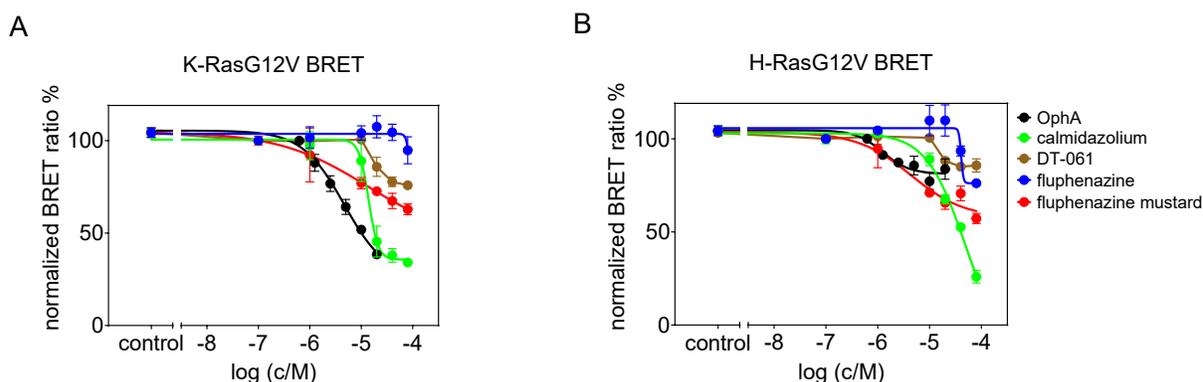

Table 8. IC50 values of compounds assessed in 3D synergism spheroid assays

Compound	NCI H358 IC₅₀ ± SEM/ μM	A375 IC₅₀ ± SEM/ μM	MDA-MB-231 IC₅₀ ± SEM/ μM
DT-061	2.65 ± 0.25	2.1 ± 0.6	3 ± 0
CMZ	1.295 ± 0.005	1.3 ± 0.2	1.37 ± 0.76
CMZ + DT-061 (1 μM)	0.46 ± 0.03	0.7 ± 0.4	0.67 ± 0.06
CMZ + DT-061 (2 μM)	0.34 ± 0.05	0.6 ± 0.4	0.44 ± 0.21
trifluoperazine	0.7 ± 0.3	0.31 ± 0.06	0.59 ± 0.22
ARS-1620	0.5 ± 0.1	52 ± 4	58 ± 6

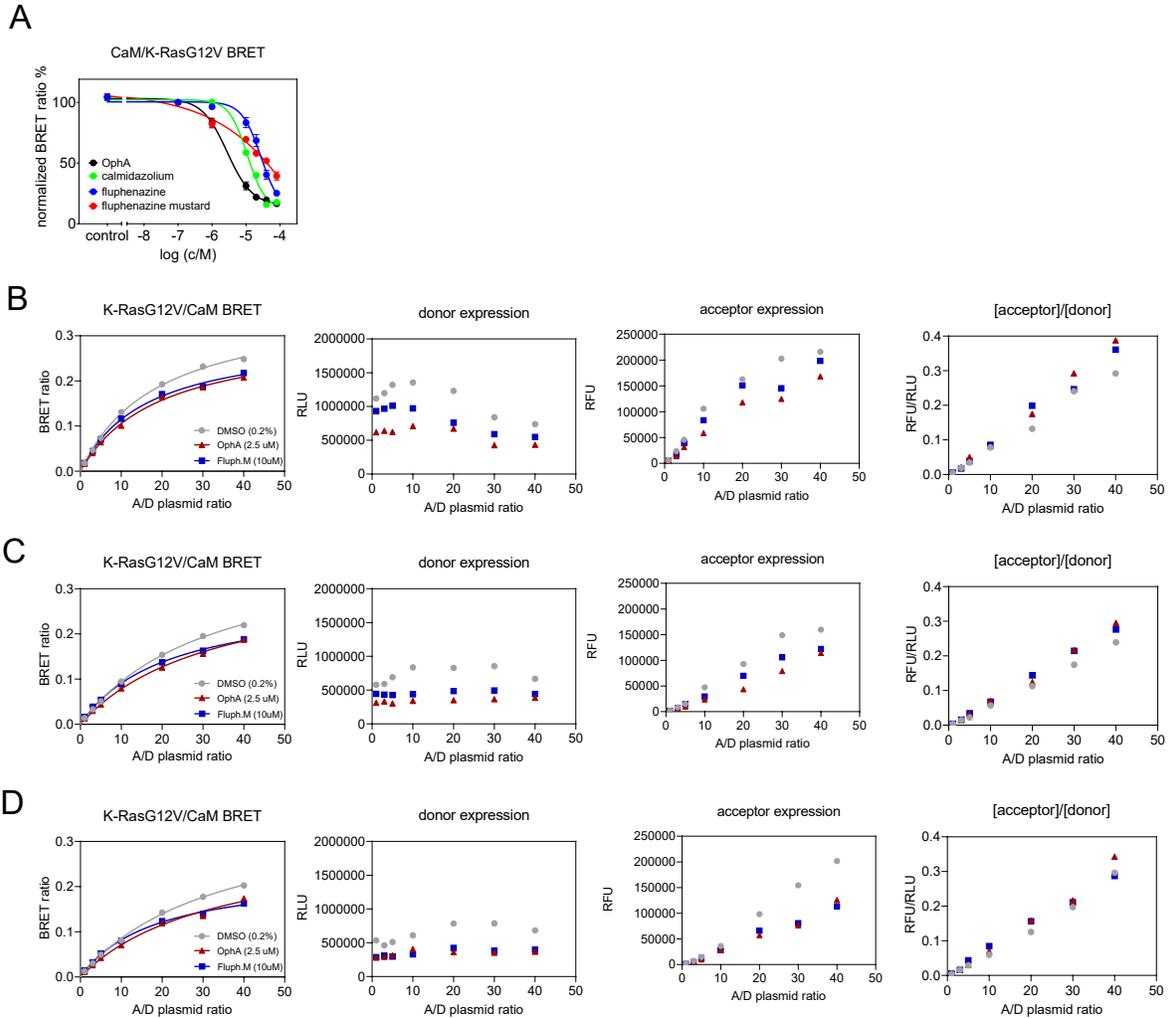

Supplementary Figures

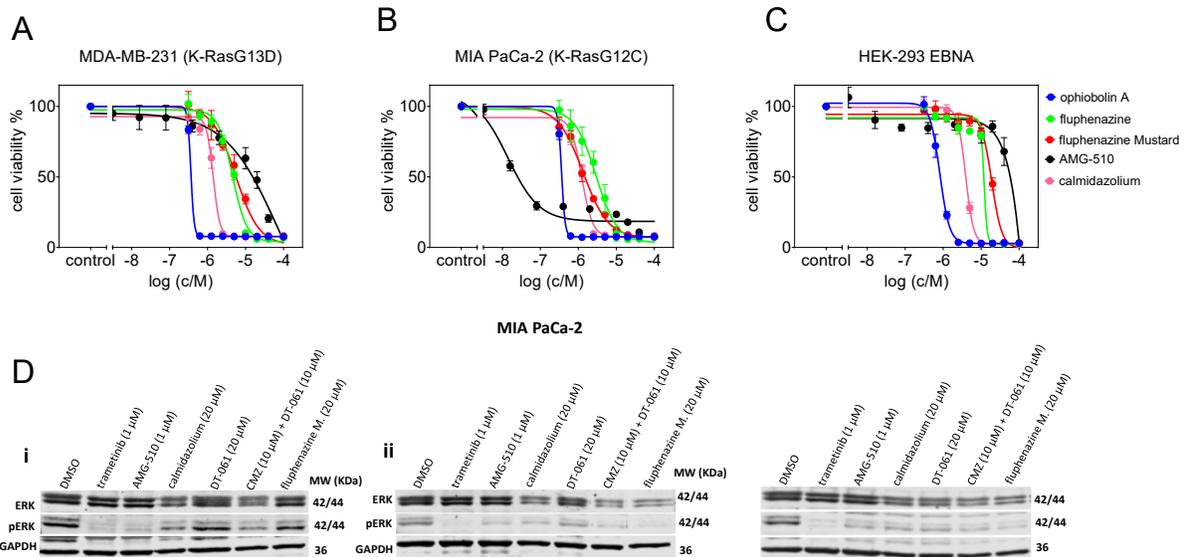

SI Figure 1. Synergistic assessment of CaM inhibitor and PP2A activator in Ras/MAPK mutated cancer cell lines. (A-C) Dose response curves for various inhibitors in Ras pathway mutant cell lines NCIH-358 (A), A 375 (B) and MDA-MB-231 (C). Compounds were tested as either single agents at concentration ranges of 0.2 μ M – 10 μ M (calmidazolium), 0.6 μ M – 40 μ M (DT-061), 0.2 μ M – 40 μ M (trifluoperazine) and 0.6 μ M – 40 μ M (ARS-1620) or in combination at a full dose response range of 0.2 μ M – 10 μ M for calmidazolium plus 1 or 2 μ M of DT-061 added to all test conditions. Data represent mean values \pm SEM, $n = 2$. The data were fit into $\log(\text{inhibitor})$ vs. variable response (four parameters) function was used in the Prism (GraphPad) software to obtain the dose response curve. The actual curve fitting for Bliss calculation was done on the SynergyFinder website (<https://synergyfinder.fimm.fi/>). (D) Bliss synergism scores for combinatorial calmidazolium and DT-061 effects in Ras mutant cancer cell lines Data represent mean values \pm SEM, $n = 2$

SI Figure 2. Cellular BRET assays indicates fluphenazine mustard inhibits both K-Ras and H-Ras nanoclustering. (A,B) Dose response curves of phenothiazines (0.1 – 80 μ M), calmidazolium (0.1 – 80 μ M), DT-061 (0.1 – 80 μ M) and OphA (0.3 – 20 μ M) on K-RasG12V (A) and H-RasG12V (B) nanoclustering BRET. The A/D plasmid ratio was 4/1. Data represent mean values \pm SEM, $n \geq 3$. The data were fit into $\log(\text{inhibitor})$ vs. variable response (four parameters) function was used in the Prism (GraphPad) software to obtain the dose response curve. The actual curve fitting for DSS₃ calculation was done on the breeze-site (<https://breeze.fimm.fi/>).

SI Figure 3. Assessment of the K-Ras/CaM on-target effects of CaM inhibitors and phenothiazines. (A) Dose-response analysis of fluphenazine and its covalent mustard (0.1 – 80 μ M) derivative as compared to OphA and calmidazolium (0.1 – 80 μ M) using *Rluc8-K-RasG12V/ GFP2-CaM* BRET assay. The A/D plasmid ratio was 9/1. Data represent mean values \pm SEM, $n \geq 2$. The data were fit into $\log(\text{inhibitor})$ vs. variable response (four parameters) function was used in the Prism (GraphPad) software to obtain the dose response curve. The actual curve fitting for DSS_3 calculation was done on the breeze-site (<https://breeze.fimm.fi/>). **(B-D)** Data from BRET pairs of *Rluc8-K-RasG12V* and *GFP2-CaM* after 24h treatment with DMSO (0.2% v/v in growth medium), OphA (2.5 μ M) or fluphenazine mustard (10 μ M). Each figure group represents individual biological repeats with (left to right) BRET ratio plotted against acceptor/donor plasmid ratio (A/D plasmid ratio), and then donor expression (RLU), acceptor expression (RFU) and relative expression of the two (RFU/RLU) plotted against acceptor/donor plasmid ratio (A/D plasmid ratio). Each biological repeat is the mean of four technical replicates (\pm SEM). The BRET ratio vs. relative expression data were fit with a hyperbolic function in Prism to obtain the $BRET_{max}$ and $BRET_{50}$ values.

SI Figure 4. Phenotypic and signaling effects of inhibitors on Ras/MAPK mutated cancer cells. (A-C) Comparison of effects of compounds on 2D monolayers derived from MDA-MB-231 (A), MIA PaCa-2 (B) and HEK-293 EBNA (C). Cells were treated with concentration range of 0.6 μM – 80 μM (fluphenazine and fluphenazine mustard), 0.3 μM – 40 μM (calmidazolium and OphA) and 0.003 μM – 40 μM (AMG-510). Data represent mean values ± SEM, n = 3. The data were fit to log (inhibitor) vs response – variable slope (four parameters) equation using the Prism (GraphPad) software. (D) MAPK signaling output measurement in MIA PaCa-2 upon treatment with control compounds trametinib (1 μM) and AMG-510 (1 μM), single agent treatment with camidazolium (20 μM) and DT-061 (20 μM) or in combination (DT-061 10 μM + CMZ 10 μM) as well as fluphenazine mustard (20 μM). pERK/ERK levels were assessed using a mouse monoclonal antibody against pERK and a rabbit polyclonal antibody against ERK. GAPDH was used as endogenous control for protein expression. Cells were seeded in 6-well plates for 24hrs, serum starved, treated with indicated concentrations of inhibitors for 2 h and then stimulated with EGF for 10 min. Blots shown represent images from 3 independent biological repeats.
