# General description of Finite Mixture models

We have a collection of individual trajectories.

We try to divide the population into a number of homogenous sub-populations and to estimate, at the same time, a typical trajectory for each sub-population. (Nagin 2005)

This model can be interpreted as functional fuzzy logic cluster analysis.

## The basic model (Nagin 2005)

Consider a population of size  $N$  and a variable of interest  $Y$ .

Let  $Y_i = y_{i1}, y_{i2}, \dots, y_{iT}$  be  $T$  measures of the variable, taken at times  $t_1, \dots, t_T$  for subject number  $i$  and  $\pi_k$  the probability of a given subject to belong to group number  $k$

**For a given group  $G_k$ , we suppose conditional independence for the sequential realizations of the elements  $y_{it}$  over the  $T$  periods of measurements.**

The density  $f$  of  $Y$  is given by

$$f(y_i; \psi) = \sum_{k=1}^K \pi_k g^k(y_i; \Theta_k), \quad (1)$$

where  $g^k(\cdot)$  denotes the distribution of  $y_{it}$  conditional on membership in group  $k$  and the role of the parameters  $\Theta_k$  is to describe the shape of the trajectories in group  $k$ .

# Possible data distributions

- Poisson distribution
- Binary logit distribution
- (Censored) normal distribution
- Beta distribution (Noel & S. 2023)

# Likelihood function for a normal distribution

Notations:

- $\beta^j t = \beta_0^j + \beta_1^j t + \beta_2^j t^2 + \beta_3^j t^3 + \beta_4^j t^4$ .
- $\phi$ : density of standard centered normal law.

Then,

$$L = \frac{1}{\sigma} \prod_{i=1}^N \sum_{j=1}^r \pi_j \prod_{t=1}^T \phi \left( \frac{y_{it} - \beta^j t}{\sigma} \right). \quad (2)$$

It is too complicated to get closed-forms equations.

SAS procedure proc Traj (Nagin & Jones 2008).

# Predictors of trajectory group membership

$X$  : vector of variables potentially associated with group membership.

$$\pi_k(x_i) = \frac{e^{x_i \theta_k}}{\sum_{k=1}^K e^{x_i \theta_k}}, \quad (3)$$

where  $\theta_k$  denotes the effect of  $x_i$  on the probability of group membership for group  $k$ .

$$L = \prod_{i=1}^N \sum_{k=1}^K \frac{e^{x_i \theta_k}}{\sum_{k=1}^K e^{x_i \theta_k}} \prod_{t=1}^T g^k(y_{it}). \quad (4)$$

## Adding covariates to the trajectories

Let  $W$  be a vector of covariates potentially influencing  $Y$ .

The likelihood then becomes

$$L = \prod_{i=1}^N \sum_{k=1}^K \frac{e^{x_i \theta_k}}{\sum_{k=1}^K e^{x_i \theta_k}} \prod_{t=1}^T p^k(y_{it} | A_i, W_i, \Theta_k).$$

# Salary groups: Men versus women (S. 2016)

## Generalized finite mixture model (S. 2015)

Let  $x_1 \dots x_M$  and  $z_t$  be covariates potentially influencing  $Y$ .

We propose the following model:

$$y_{it} = \left( \beta_0^j + \sum_{l=1}^M \alpha_{0l}^j x_{il} + \gamma_0^j w_{it} \right) + \left( \beta_1^j + \sum_{l=1}^M \alpha_{1l}^j x_{il} + \gamma_1^j w_{it} \right) t \\ + \left( \beta_2^j + \sum_{l=1}^M \alpha_{2l}^j x_{il} + \gamma_2^j w_{it} \right) t^2 + \left( \beta_3^j + \sum_{l=1}^M \alpha_{3l}^j x_{il} + \gamma_3^j w_{it} \right) t^3 \\ + \left( \beta_4^j + \sum_{l=1}^M \alpha_{4l}^j x_{il} + \gamma_4^j w_{it} \right) t^4 + \varepsilon_{it}^j,$$

where  $\varepsilon_{it} \sim \mathcal{N}(0, \sigma^j)$ ,  $\sigma^j$  being the standard deviation, constant in group  $j$ .

## Statistical Properties (S. 2015)

The model's estimated parameters are the result of maximum likelihood estimation. As such, they are consistent and asymptotically normally distributed.

Confidence intervals of level  $\alpha$  for the parameters  $\beta_k^j$ :

$$CI_{\alpha}(\beta_k^j) = \left[ \hat{\beta}_k^j - t_{1-\alpha/2; N-(2+M)s} ASE(\hat{\beta}_k^j); \hat{\beta}_k^j + t_{1-\alpha/2; N-(2+M)s} ASE(\hat{\beta}_k^j) \right]. \quad (5)$$

Confidence intervals of level  $\alpha$  for the disturbance factor  $\sigma_j$ :

$$CI_{\alpha}(\sigma_j) = \left[ \sqrt{\frac{(N - (2 + M)s - 1)\hat{\sigma}_j^2}{\chi_{1-\alpha/2; N-(2+M)s-1}^2}}; \sqrt{\frac{(N - (2 + M)s - 1)\hat{\sigma}_j^2}{\chi_{\alpha/2; N-(2+M)s-1}^2}} \right]. \quad (6)$$

# The Beta distribution

Figure 1 – *Example of different shapes of the Beta density for some parameters.*

# Underlying Beta distribution

Density of  $y_{it}$  conditional to membership in group  $C_k$  :

$$g_k(y_{it}; \mu_{kit}, \phi_{kit}) = \frac{\Gamma(\phi_{kit})}{\Gamma(\mu_{kit}\phi_{kit})\Gamma((1-\mu_{kit})\phi_{kit})} y_{it}^{\mu_{kit}\phi_{kit}-1} (1-y_{it})^{(1-\mu_{kit})\phi_{kit}-1},$$

with

$$\mu_{kit} = \frac{e^{\beta_k A_{it} + \delta_k W_{it}}}{1 + e^{\beta_k A_{it} + \delta_k W_{it}}} \text{ and } \phi_{kit} = \zeta_k A_{it}. \quad (8)$$

Likelihood of the data:

$$L = e^{\prod_{i=1}^n \left( \sum_{k=1}^K \pi_k \prod_{t=1}^T \frac{\Gamma(\phi_{kit})}{\Gamma(\mu_{kit}\phi_{kit})\Gamma((1-\mu_{kit})\phi_{kit})} y_{it}^{\mu_{kit}\phi_{kit}-1} (1-y_{it})^{(1-\mu_{kit})\phi_{kit}-1} \right)}. \quad (9)$$

# Data

Data from 190 countries from "Our World In Data".

Main variable of interest: **contamination rate**. We create a panel with monthly data from January 2020 till April 2021.

Covariates: new cases, population size (in million inhabitants), total cases per million people, median age of the population, population density, number of inhabitants over 65 (in million inhabitants), government response stringency index, GDP per capita, extreme poverty index, cardiovascular death rate, diabetes prevalence rate, index of handwashing facilities, rate of hospital beds per thousand inhabitants, life expectancy, index of human development and stringency index.

The nine metrics used to calculate the **stringency index** are: school closures; workplace closures; cancellation of public events; restrictions on public gatherings; closures of public transport; stay-at-home requirements; public information campaigns; restrictions on internal movements; and international travel controls.

# Individual trajectories

Figure 2 – *Contamination rates for all countries.*

## Model selection

Kass and Wasserman's criterion: Let  $p_k$  be the probability that a model with  $k$  groups is the correct model. They show that  $p_k$  can be approximated by

$$p_k \approx \frac{e^{BIC_k - BIC_{max}}}{\sum_k e^{BIC_k - BIC_{max}}}.$$

- 4 Multiple Trajectory Analysis**
- 5 Identifiability of Finite Mixture Models

# Basic Idea

We conjointly analysis the trajectories of  $J$  variables  $Y^1, \dots, Y^J$ .

# The model

We suppose the trajectories for a variable  $Y^l$  can be linked to trajectories for all other variables  $Y^j, j \neq l$ . Then,

$$P(Y_i^1, \dots, Y_i^J | A_i, W_i) = \sum_{(k_1, \dots, k_J) \in K_1 \times \dots \times K_J} \pi_{k_J | k_1 \dots k_{J-1}} \times \dots \times \pi_{k_2 | k_1} \times \pi_{k_1} \\ \prod_{j=1}^J \prod_{t=1}^T p^{k_j}(y_{it}^j | A_i, W_i, \Theta_k^j),$$

where  $\pi_{k_j | k_1 \dots k_{j-1}}$  is the probability of belonging to group  $j$  conditional on the membership to groups 1 to  $j - 1$ .

# Membership Probability

$$\pi_{k_1} = \frac{e^{\theta_{k_1} x_i}}{\sum_{k_1=1}^{K_1} e^{\theta_{k_1} x_i}}, \quad \pi_{k_2|k_1} = \frac{e^{\theta_{k_2}^{k_1} w_i^{k_2}}}{\sum_{k_2=1}^{K_2} e^{\theta_{k_2}^{k_1} w_i^{k_2}}}, \quad \dots,$$
$$\pi_{k_J|k_1 \dots k_{J-1}} = \frac{e^{\theta_{k_J}^{k_1 \dots k_{J-1}} w_i^{k_J}}}{\sum_{k_J=1}^{K_J} e^{\theta_{k_J}^{k_1 \dots k_{J-1}} w_i^{k_J}}}.$$

One drawback of this method is the great expansion of the number of parameters and the fact that the parameters are hardly interpretable.

## A new approach

Denote by  $Z_i = (Z_{i1}, \dots, Z_{iJ})$  the vector containing the group membership of individual  $i$  for the variables  $Y^1, \dots, Y^J$ .  $Z_i \in \llbracket 1; K_1 \rrbracket \times \dots \times \llbracket 1; K_J \rrbracket$ .

Then,

$$P\left(Z_{ij} = k \mid z_{ih} \text{ for } h \neq j, X_i^j\right) = \frac{e^{B_{ij,k}}}{\sum_{h=1}^{K_j} e^{B_{ij,h}}},$$

where  $B_{ij,k} = \alpha_{j,k} + \beta_{j,k} X_i^j + \sum_{h \neq j} \psi_{jh,kz_{ih}}$ .

- $\alpha_{j,k}$  is a choice specific intercept ;
- $\beta_{j,k}$  is a vector corresponding to the covariate  $X_i^j$  ;
- $z_{ih}$  the group membership of the individual  $i$  for  $Y^h$  ;
- $\psi_{jh,kl}$  is an association parameter between belonging to group  $k$  for  $Y^j$  and belonging to the group  $l$  for  $Y^h$ .

## Number of parameters

The Hammersley-Clifford Theorem allows to write the conditional probabilities as

$$P\left(Z_{ij} = k \mid z_{ih} \text{ for } h \neq j, X_i^j\right) = \frac{e^{B_{ij,k}}}{\sum_{h=1}^{K_j} e^{B_{ij,h}}}$$

where  $B_{ij,k} = \alpha_{j,k} + \beta_{j,k} X_i^j + \sum_{h < j} \psi_{hj, z_{ih} k} + \sum_{h > j} \psi_{jh, k z_{ih}}$ .

### Proposition

The numbers of parameters is

$$\sum_{j=1}^J (K_j - 1) \times (\text{ncol}(X_i^j) + 1) + \sum_{1 \leq j \neq j' \leq J} (K_j - 1)(K_{j'} - 1).$$

## A simulation example

We simulate trajectories for 200 individuals and 3 variables.

- $Y^1$  (normal distribution) :  $\beta_{1,1} = (3.53, -2.25, 0.47)$ ,  
 $\beta_{1,2} = (-1.62, 3.9, -0.65)$ ,  $\beta_{1,3} = (0.263, 0.036, 0.01)$ ,  
 $\sigma_{1,1} = \sigma_{1,2} = \sigma_{1,3} = 1$  ;
- $Y^2$  (ZIP distribution) :  $\beta_{2,1} = (1.2, 2.3, -1.2, 0.5, -0.1)$ ,  $\beta_{2,2} = (2)$ ,  
 $\beta_{2,3} = (-7.5, 0, 2.2, -0.4)$ ,  $\nu_1 = (-2, 1)$ ,  $\nu_2 = (-1, 0.1)$ ,  $\nu_3 = (0, -1)$ ;
- $Y^3$  (logit distribution) :  $\beta_{3,1} = (6.32, -5.8, 1)$ ,  $\beta_{3,2} = (-6.69, 1.92)$ .

Furthermore, we choose all  $\theta_{j,k} = 0$  and  $\psi = (-3, 3, 4, 0, -2, 5, 1, 0)$ . We launch trajER for each variable separately and we use the results as initial values for the multi-trajectory model.

# Identifiability

## Definition:

A finite mixture model is identifiable if a given data set leads to a uniquely determined set of model parameter estimations up to a permutation of the clusters.

Identifiability of the parameters is a necessary condition for the existence of consistent estimators for any statistical model.

Without identifiability, there might be several solutions for the parameter estimation problem.

# Notations

Distribution  $f$  of a finite mixture model:

$$f(y_i; \Omega) = \sum_{k=1}^K \pi_k g_k(y_i; \theta^k).$$

Cumulative distribution function  $F$  of a finite mixture model:

$$F(y_i; \Omega) = \sum_{k=1}^K \pi_k G_k(y_i; \theta^k).$$

## Mixtures and mixing distributions

Let  $\mathcal{F} = \{F(y; \omega), y \in \mathbb{R}^T, \omega \in \mathbb{R}_K^{s+2}\}$  be a family of  $T$ -dimensional cdf's indexed by a parameter set  $\omega$ , such that  $F(y; \omega)$  is measurable in  $\mathbb{R}^T \times \mathbb{R}_K^{s+2}$ .

The the  $s + 2$ -dimensional cdf  $H(x) = \int_{\mathbb{R}_K^{s+2}} F(y; \omega) dG(\omega)$  is the image of the above mapping, of the  $s + 2$ -dimensional cdf  $G$ .

The distribution  $H$  is called the mixture of  $\mathcal{F}$  and  $G$  its mixing distribution.

Let  $\mathcal{G}$  denote the class of all  $s + 2$ -dimensional cdf's  $G$  and  $\mathcal{H}$  the induced class of mixtures  $H$ .

Then  $\mathcal{H}$  is identifiable if  $Q$  is a one-to-one map from  $\mathcal{G}$  onto  $\mathcal{H}$ .

# Characterization of identifiability

The set  $\mathcal{H}$  of all finite mixtures of class  $\mathcal{F}$  of distributions is the convex hull of  $\mathcal{F}$ .

$$\mathcal{H} = \left\{ H(y) : H(y) = \sum_i c_i F(y, \omega_i), c_i > 0, \sum_i c_i = 1, F(y, \omega_i) \in \mathcal{F} \right\}. \quad (10)$$

## Theorem

*A necessary and sufficient condition for the class  $\mathcal{H}$  of all finite mixtures of the family  $\mathcal{F}$  to be identifiable is that  $\mathcal{F}$  is a linearly independent family over the field of real numbers.*

# The Model

$$Y_{it} = f(\mathbf{a}_{it}; \beta^k, \delta^k) + \varepsilon_{it}^k = \beta^k A_{it} + \delta^k W_{it} + \varepsilon_{it}^k. \quad (11)$$

We can write

$$\mathcal{L}((Y_i)_{i \in I}) = \bigotimes_{i \in I} F_{A_i, W_i, J}. \quad (12)$$

Identifiability of a model means that knowing the data distribution  $\mathcal{L}(Y_i), i \in I$ , one can uniquely identify the mixing distribution  $J$ .

That is, no two distinct sets of parameters lead to the same data distribution.

# Nagin's base model

$$\mathcal{C}_1 = \left( F_{A,J} : F_{A,J} = \bigotimes_{i \in I} F_{A_i,J} \right)_{J \in \Omega_1}$$

## Theorem

Let  $h_j = \min \{ q : \{A_{ij}, i \in I\} \subseteq \cup_{i=1}^q H_i \mid H_i \in \mathcal{H}_{n-1} \}$ .

If there exist  $j$  such that  $|S(J)| < h_j, \forall J$  then  $\mathcal{C}_1$  is identifiable.

## Adding covariates independent of cluster membership

$$\mathcal{C}_2 = \left( F_{A,J} : F_{A,J} = \bigotimes_{i \in I} F_{A_i, W_{i,J}} \right)_{J \in \Omega_1}, \quad (13)$$

$$\mathcal{C}_{2A} = \left( F_{A,J} : F_{A,J} = \bigotimes_{i \in I} F_{A_i, J} \right)_{J \in \Omega_1}, \quad (14)$$

$$\mathcal{C}_{2W} = \left( F_{A,J} : F_{A,J} = \bigotimes_{i \in I} F_{W_{i,J}} \right)_{J \in \Omega_1}. \quad (15)$$

### Theorem

*If  $\mathcal{C}_{2A}$  and  $\mathcal{C}_{2W}$  are identifiable and  $W_{ij}$  is not a multiple of  $A_{ij}$ , for all  $i, j$ , then  $\mathcal{C}_2$  is identifiable.*

# Numerical Example

- Two clusters with sizes  $\pi_1 = \pi_2 = \frac{1}{2}$ .
- Two time-points 1 and 2.
- Same variability in both clusters  $\sigma = 0.1$

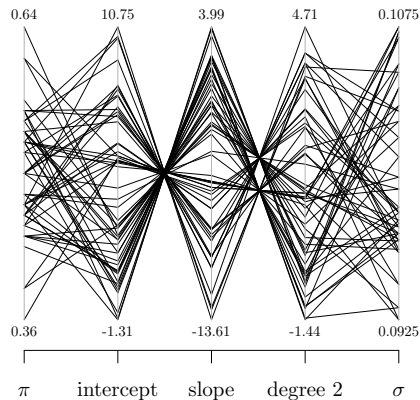

We simulate 50 samples of 100 trajectories with parameters

- $\beta^1 = (3, -2)$  and  $\beta^2 = (0, 2)$  (linear model)
- $\beta^1 = (10, -12.5, 3.5)$  and  $\beta^2 = (-2, 5, -1)$  (polynomial model).

# Parallel coordinate plots of the estimated parameter

Linear Model

Parabolic Model

# The generalized model

## Theorem

*The model is identifiable if*

- $d_k < T$  for all  $1 \leq k \leq K$  and all  $a_{it}$  are distinct, for all  $i_t$ .
- $W_k$  has full rank for all  $1 \leq k \leq K$ .
- $rk(A_k, W_k) = rk(A_k) + rk(W_k)$ , for all  $1 \leq k \leq K$ .

# Numerical Example

- Two clusters with sizes  $\pi_1 = \pi_2 = \frac{1}{2}$ .
- Two time-points 1 and 2.
- Same variability in both clusters  $\sigma = 0.1$
- Shape description parameters  $\beta_1 = (3, -2)$ ,  $\beta_2 = (0, 2)$ ,  $\delta_1 = 2$  and  $\delta_2 = -3$ .

We simulate 50 samples of 100 trajectories for 3 types of models:

- The covariate is independent of time and only takes values 0 or 1
- The covariate is time dependent but in a nonlinear way
- The covariate is time dependent in a linear way
